Communication System

Base−band Modulation   Carrier Modulation

Carrier Modulation

Amplitude (AM)   Angle

Frequency (FM)   Phase (PM)

Modulationisoperationperformedatthetransmittertoachieveefficientandreliable information transmission.

For analogmodulation, it is frequencytranslationmethodcausedbychangingtheappropriate quantity in a carrier signal.

 It involvestwo waveforms:

- Amodulatingsignal/basebandsignal–representsthemessage.
- Acarriersignal–depends ontypeofmodulation.

•Once this information is received, the low frequency information must be removed fromthe high frequency carrier. •This process is known as "Demodulation".

Need forModulation:

- Basebandsignalsareincompatiblefordirecttransmissionoverthemediumso, modulation is used to convey (baseband) signals from one place to another.
- Allowsfrequencytranslation:
  - o FrequencyMultiplexing
  - o Reducetheantennaheight
  - o Avoidsmixingofsignals
  - o Narrowbanding
- Efficienttransmission
- Reducednoiseandinterference

Typesof Modulation:

Threemaintypesofmodulations:

Analog Modulation

- **Amplitudemodulation**

Example: Double sideband with carrier (DSB-WC), Double- sidebandsuppressed carrier (DSB-SC), Single sideband suppressed carrier (SSB-SC), vestigial sideband (VSB)

- **Anglemodulation(frequencymodulationλ&phase modulation)**

    Example:Narrowbandfrequencymodulation(NBFM), Widebandλ frequency modulation (WBFM), Narrowband phase modulation (NBPM), Wideband phase modulation (NBPM)

PulseModulation

- Carrierisatrainofpulses
- Example:PulseAmplitudeModulation(PAM),Pulsewidthmodulation(PWM), Pulse Position Modulation (PPM)

Digital Modulation

- Modulatingsignalisanalog
    - Example: Pulse Code Modulation(PCM), Delta Modulationλ (DM), Adaptive Delta Modulation (ADM), Differential Pulse Code Modulation (DPCM), Adaptive Differential Pulse Code Modulation (ADPCM) etc.
- Modulatingsignalisdigital(binarymodulation)
    - Example: Amplitude shift keying (ASK), frequency Shift Keyingλ (FSK), Phase Shift Keying (PSK) etc

FrequencyDivision Multiplexing

Multiplexing is the name given to techniques, which allow more than one message to be transferred via the same communication channel. The channel in this context could be a transmission line, *e.g.* a twisted pair or co-axial cable, a radio system or a fibre optic system *etc*.

FDM isderived fromAMtechniques inwhichthe signalsoccupythesamephysical'line' but indifferent frequencybands. Eachsignaloccupies itsownspecific bandoffrequenciesallthe time, *i.e.* the messages share the channel **bandwidth**.

- FDM–messagesoccupy**narrow** bandwidth– all thetime.

Multiplexing requires that the signals be kept apart so that they do not interfere with each other, and thus they can be separated at the receiving end. This is accomplished by separating the signal either in frequency or time. The technique of separating the signals in frequency is referred to as frequency-division multiplexing (FDM), whereas the technique of separating the signals in time is called time-division multiplexing. In this section, we discuss frequency division multiplexing systems, referred hereafter as FDM.

Fig. 1   shows the block diagram of FDM system. As shown in the Fig. 1   , input message signals, assumed to be of the low-pass type are passed through input low-pass filters. This filtering action removes high-frequency components that do not contribute significantly to signal representation but may disturb other message signals that share the common channel. The filtered message signals are then modulated with necessary carrier frequencies with the help of modulators. The most commonly method of modulation in FDM is single sideband modulation, which requires a bandwidth that is approximately equal to that of original message signal. The band pass filters following the modulators are used to restrict the band of each modulated wave to its prescribed range. The outputs of band-pass filters are combined in parallel which form the input to the common channel.

At the receiving end, bandpass filters connected to the common channel separate the message signals on the frequency occupancy basis. Finally, the original message signals are recovered by individual demodulators.

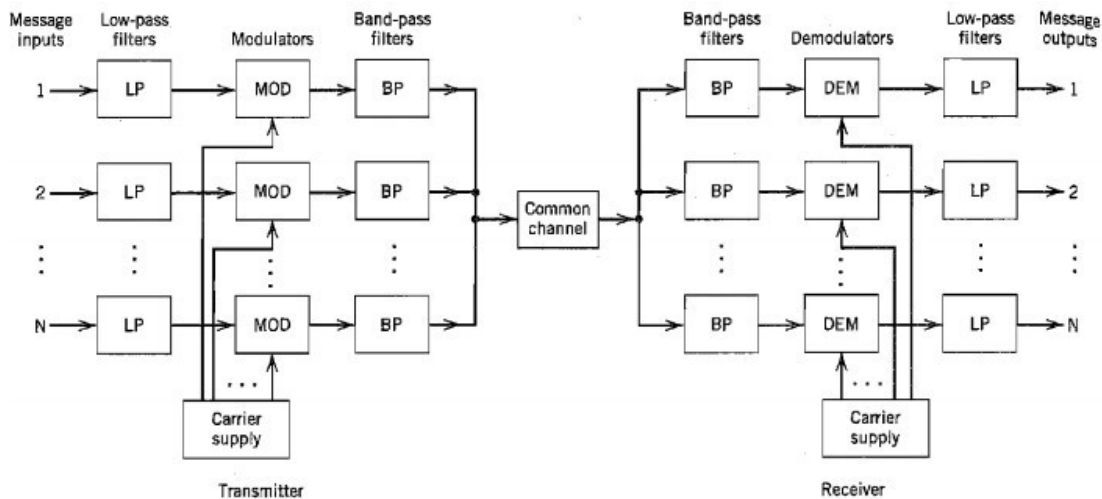

Fig.1. FrequencyDivisionMultiplexing

AmplitudeModulation(AM)

Amplitude Modulation is the process of changing the amplitude of a relatively highfrequency carrier signal in accordance with the amplitude of the modulating signal (Information).

The carrier amplitude varied linearly by the modulating signal which usually consists of a range of audio frequencies. The frequency of the carrier is not affected.

- ApplicationofAM-Radiobroadcasting,TVpictures(video),facsimiletransmission
- FrequencyrangeforAM-535kHz – 1600kHz
- Bandwidth-10kHz

Various formsofAmplitude Modulation

• Conventional AmplitudeModulation (Alternatively known asFull AM or Double SidebandLargecarrier modulation(DSBLC)/DoubleSidebandFullCarrier(DSBFC)

• DoubleSidebandSuppressedcarrier(DSBSC) modulation

• SingleSideband(SSB) modulation

• VestigialSideband(VSB) modulation

TimeDomainandFrequencyDomainDescription

Itistheprocesswhere, theamplitudeofthecarrier is variedproportionaltothatofthe message signal.

Let m (t) be the base-band signal,m (t) $\longleftrightarrow$ M (ω) and c (t) be the carrier, c(t) = $A_c\cos(\omega_c t)$.fcischosensuchthatfc$>>$W,whereWisthemaximumfrequencycomponentof m(t).Theamplitudemodulatedsignalisgivenby

$$s(t)=Ac[1+k_a m(t)]\cos(\omega ct)$$

Fourier Transform on both sides of the above equation

$$S(\omega) =\pi Ac/2 \ (\delta(\omega -\omega c) +\delta(\omega+\omega c)) +k_a Ac/ \ 2 \ (M(\omega -\omega c)+M(\omega +\omega c)) \ k_a \text{is a}$$

constant called amplitude sensitivity.
$k_a m(t)<1$anditindicatespercentagemodulation.

Fig.2.Amplitude modulationintimeand frequencydomain

SingleTone Modulation:

Consider a modulating wave m(t) that consists of a single tone or single frequency component given by

$$m(t) = A_m \cos(2\pi f_m t) \qquad \text{...............(1)}$$

where A_m is peak amplitude of the sinusoidal modulating wave

f_m is the frequency of the sinusoidal modulating wave

Let A_c be the peak amplitude and f_c be the frequency of the high frequency carrier signal. Then the corresponding single-tone AM wave is given by

$$s(t) = A_c[1 + m\cos(2\pi f_m t)]Cos(2\pi f_c t) \qquad \text{...............(2)}$$

Let A_{max} and A_{min} denote the maximum and minimum values of the envelope of the modulated wave. Then from the above equation (2.12), we get

$$\frac{A_{max}}{A_{min}} = \frac{A_c(1+m)}{A_c(1-m)}$$

$$m = \frac{A_{max} - A_{min}}{A_{max} + A_{min}}$$

Expanding the equation(2),we get

$$s(t) = A_c \cos(2\pi f_c t) + \frac{1}{2}mA_c \cos[2\pi(f_c + f_m)t] + \frac{1}{2}mA_c \cos[2\pi(f_c - f_m)t]$$

The Fourier transform of $s(t)$ is obtained as follows.

$$s(f) = \frac{1}{2}A_c[\delta(f - f_c) + \delta(f + f_c)] + \frac{1}{4}mA_c[\delta(f - f_c - f_m) + \delta(f + f_c + f_m)]$$

$$+ \frac{1}{4}mA_c[\delta(f - f_c + f_m) + \delta(f + f_c - f_m)]$$

Thus the spectrum of an AM wave, for the special case of sinusoidal modulation consists of delta functions at $\pm f_c$, $f_c \pm f_m$, and $-f_c \pm f_m$. The spectrum for positive frequencies is as shown in figure
Fig.3.FrequencyDomaincharacteristicsofsingletoneAM

PowerrelationsinAMwaves:

Considertheexpressionforsingletone/sinusoidalAMwave

$$s(t) = A_c Cos(2\pi f_c t) + \frac{1}{2} m A_c Cos[2\pi (f_c + f_m)t] + \frac{1}{2} m A_c Cos[2\pi (f_c - f_m)t] \quad \cdots\cdots(1)$$

This expression contains three components. They are carrier component, upper side band and lower side band. Therefore Average power of the AM wave is sum of these three components.

Therefore the total power in the amplitude modulated wave is given by

$$Pt = \frac{V^2_{car}}{R} + \frac{V^2_{LSB}}{R} + \frac{V^2_{USB}}{R} \quad \cdots\cdots\cdots(2)$$

Where all the voltages are rms values and R is the resistance, in which the power is dissipated.

$$P_C = \frac{V^2_{car}}{R} = \frac{\left(A_c / \sqrt{2}\right)^2}{R} = \frac{A_c^2}{2R}$$

$$P_{LSB} = \frac{V_{LSB}^2}{R} = \left(\frac{mA_c}{2\sqrt{2}}\right)^2 \frac{1}{R} = \frac{m^2 A_c^2}{8R} = \frac{m^2}{4} P_c$$

$$P_{USB} = \frac{V_{USB}^2}{R} = \left(\frac{mA_c}{2\sqrt{2}}\right)^2 \frac{1}{R} = \frac{m^2 A_c^2}{8R} = \frac{m^2}{4} P_c$$

Therefore total average power is given by

$$P_t = P_c + P_{LSB} + P_{USB}$$

$$P_t = P_c + \frac{m^2}{4}P_c + \frac{m^2}{4}P_c$$

$$P_t = P_c\left(1 + \frac{m^2}{4} + \frac{m^2}{4}\right)$$

$$P_t = P_c\left(1 + \frac{m^2}{2}\right) \quad \text{..........................(3)}$$

The ratiooftotalside bandpowertothetotalpowerinthe modulatedwaveisgivenby

$$\frac{P_{SB}}{P_t} = \frac{P_c\left(m^2/2\right)}{P_c\left(1 + m^2/2\right)}$$

$$\frac{P_{SB}}{P_t} = \frac{m^2}{2 + m^2} \quad \text{.......................(4)}$$

ThisratioiscalledtheefficiencyofAMsystem Generation of

AM waves:

Twobasicamplitudemodulationprinciplesarediscussed.Theyaresquarelawmodulation and switching modulator.

SquareLawModulator

When the output of a device is not directly proportional to input throughout the operation,thedevice issaidto benon-linear.TheInput-Outputrelationofanon-lineardevice can be expressed as

$$V_0 = a_0 + a_1 V_{in} + a_2 V_{in}^2 + a_3 V_{in}^3 + a_4 V_{in}^4 + \text{........}$$

When the in put is very small, the higher power terms can be neglected. Hence the output is approximately given by $V_0 = a_O + a_1 V_{in} + a_2 V_{in}^2$

Whentheoutputisconsidereduptosquareoftheinput,thedeviceiscalledasquarelaw device and the square law modulator is as shown in the figure 4

Fig.4.SquareLawModulator
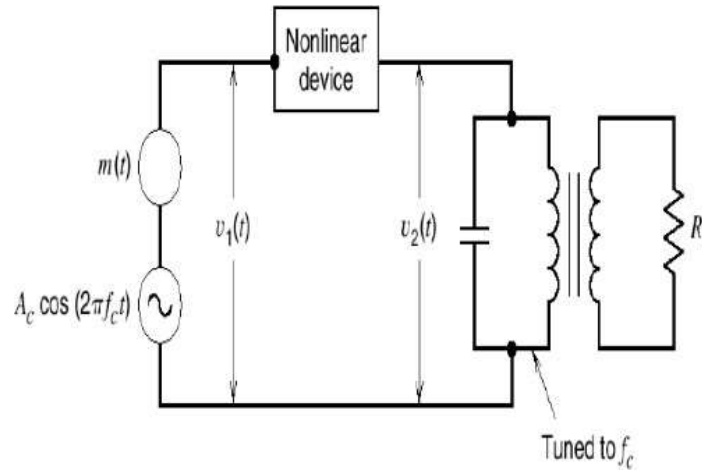

Consideranon-lineardeviceto whichacarrierc(t)=$A_c$cos($2\pi f_c$t)andaninformation signalm(t) arefedsimultaneouslyasshowninfigure 4.Thetotalinputtothedevice at any instant is

$$V_{in} = c(t) + m(t)$$

$$V_{in} = A_c \cos 2\pi f_c t + m(t)$$

As the level of the input is very small, the output can be considered up to square of the input, $i.e.$, $V_0 = a_O + a_1 V_{in} + a_2 V_{in}^2$

$$V_0 = a_0 + a_1[A_c \cos 2\pi f_c t + m(t)] + a_2[A_c \cos 2\pi f_c t + m(t)]^2$$

$$V_0 = a_0 + a_1 A_c \cos 2\pi f_c t + a_1 m(t) + \frac{a_2 A_c^2}{2}(1 + \cos 4\pi f_c t) + a_2[m(t)]^2 + 2a_2 m(t) A_c \cos 2\pi f_c t$$

$$V_0 = a_0 + a_1 A_c \cos 2\pi f_c t + a_1 m(t) + \frac{a_2 A_c^2}{2}\cos 4\pi f_c t + a_2 m^2(t) + 2a_2 m(t) A_c \cos 2\pi f_c t$$

Taking Fourier transform on both sides, we get

$$V_0(f) = (a_0 + \frac{a_2 A_c^2}{2})\delta(f) + \frac{a_1 A_c}{2}[\delta(f - f_c) + \delta(f + f_c)] + a_1 M(f) +$$

$$\frac{a_2 A_c^2}{4}[\delta(f - 2f_c) + \delta(f + 2f_c)] + a_2 M(f) + a_2 A_c[M(f - f_c) + M(f + f_c)]$$

Therefore the squarelaw device output0 V consists of the dc componentatf = 0. The informationsignalranging from0to WHzand itssecond harmonics are signalat $f_c$and $2f_c$.

Frequency band centered at f_c with a deviation of $\pm W$, Hz.

The required AM signal with a carrier frequency f_c can be separated using a band pass filter at the out put of the square law device. The filter should have a lower cut-off frequency ranging between 2W and (f_c-W) and upper cut-off frequency between (f_c+W) and 2 f_c

Therefore the filter out put is

$$s(t) = a_1 A_c \cos 2\pi f_c t + 2a_2 A_c m(t) \cos 2\pi f_c t$$

$$s(t) = a_1 A_c \left[1 + 2\frac{a_2}{a_1} m(t) \right] \cos 2\pi f_c t$$

If $m(t) = A_m \cos 2\pi f_m t$, we get

$$s(t) = a_1 A_c \left[1 + 2\frac{a_2}{a_1} A_m \cos 2\pi f_m t \right] \cos 2\pi f_c t$$

Comparing this with the standard representation of AM signal,

$$s(t) = A_c \left[1 + k_a m(t) \right] \cos(2\pi f_c t)$$

Therefore modulation index of the output signal is given by

$$m = 2\frac{a_2}{a_1} A_m$$

The output AM signal is free from distortion and attenuation only when ($f_c - W$)> 2W or $f_c > 3W$.

Spectrumis asshownbelow

Switching Modulator

Consider a semiconductor diode used as an ideal switch to which the carrier signal $c(t) = A_c \cos(2\pi f_c t)$ and information signal $m(t)$ are applied simultaneously as shown figure

Fig.5.SwitchingModulator The total input for the diode at any instant is given by

$$v_1 = c(t) + m(t)$$

$$v_1 = A_c \cos 2\pi f_c t + m(t)$$

When the peak amplitude of c(t) is maintained more than that of information signal, the operation is assumed to be dependent on only c(t) irrespective of m(t).

Whenc(t)ispositive, v2=v1sincethediodeis forwardbiased. Similarly, when c(t) is negative, v2=0 since diode is reverse biased. Based upon above operation, switching response of the diode is periodic rectangular wave with an amplitude unity and is given by

$$p(t) = \frac{1}{2} + \frac{1}{\pi} \sum_{n=-\infty}^{\infty} \frac{(-1)^{n-1}}{2n-1} \cos(2\pi f_c t (2n-1))$$

$$p(t) = \frac{1}{2} + \underset{n=0,1}{\frac{2}{\pi}} \cos(2\pi f_c t) - \underset{n=-1,+2}{\frac{2}{3\pi} \cos(6\pi f_c t)} + -$$

Therefore the diode response V_o is a product of switching response $p(t)$ and input v_1.

$$v_2 = v_1 * p(t)$$

$$V_2 = [A_c \cos 2\pi f_c t + m(t)] \left[\frac{1}{2} + \frac{2}{\pi} \cos 2\pi f_c t - \frac{2}{3\pi} \cos 6\pi f_c t + - + - \right]$$

Applying the Fourier Transform, we get

$$V_2(f) = \frac{A_c}{4} [\delta(f - f_c) + \delta(f + f_{c)}] + \frac{M(f)}{2} + \frac{A_c}{\pi} \delta(f)$$

$$+ \frac{A_c}{2\pi} [\delta(f - 2f_c) + \delta(f + 2f_c)] + \frac{1}{\pi} [M(f - f_c) + M(f + f_c)]$$

$$- \frac{A_c}{6\pi} [\delta(f - 4f_c) + \delta(f + 4f_c)] - \frac{A_c}{3\pi} [\delta(f - 2f_c) + \delta(f + 2f_c)]$$

$$- \frac{1}{3\pi} [M(f - 3f_c) + M(f + f_c)]$$

The diode output v_2 consists of

a dc component at $f = 0$.

Information signal ranging from 0 to w Hz and infinite number of frequency bands centered at f, $2f_c$, $3f_c$, $4f_c$, --------

The required AM signal centred at fc can be separated using band pass filter. The lower cut off-frequency for the band pass filter should be between w and fc-wand the upper cut-off frequency between fc+w and 2fc. The filter output is given by the equation

$$S(t) = \frac{A_c}{2}\left[1 + \frac{4}{\pi}\frac{m(t)}{A_c}\right]\cos 2\pi f_c t$$

For a single tone information, let $m(t) = A_m \cos(2\pi f_m t)$

$$S(t) = \frac{A_c}{2}\left[1 + \frac{4}{\pi}\frac{A_m}{A_c}\cos 2\pi f_m t\right]\cos 2\pi f_c t$$

Therefore modulation index, $\quad m = \frac{4}{\pi}\frac{A_m}{A_c}$

The output AM signal is free from distortions and attenuations only when *fc-w>w* or *fc>2w*.

DetectionofAM waves

Demodulationistheprocessofrecoveringthe informationsignal(base band) fromthe incoming modulated signal at the receiver. There are two methods, theyare Square law Detector and Envelope Detector

SquareLawDetector

Consideranon-lineardeviceto whichtheAMsignals(t)isapplied. Whenthe levelofs(t)is very small, output can be considered upto square of the input.

Figure: Demodulation of AM using square law device

Therefore $V_o = a_o + a_1 V_{in} + a_2 V_{in}^2$

If $m(t)$ is the information signal (0-wHz) and $c(t) = A_c \cos(2\pi f_c t)$ is the carrier, input AM signal to the non-linear device is given by

$$s(t) = A_c\left[1 + k_a m(t)\right]\cos(2\pi f_c t)$$

$$V_o = a_o + a_1 s(t) + a_2 \left[s(t) \right]^2$$

$$V_o = a_o + a_1 A_c \cos 2\pi f_c t + a_1 A_c K_a m(t) \cos 2\pi f_c t + a_2 \left[A_c \cos 2\pi f_c t + A_c k_a m(t) \cos 2\pi f_c t \right]^2$$

Applying Fourier transform on both sides, we get

$$V_o(f) = \left[a_o + \frac{a_2 A_c^2}{2} \right] \delta(f) + \frac{a_1 A_c}{2} \left[\delta(f - f_c) + \delta(f + f_c) \right]$$

$$+ \frac{a_1 A_c K_a}{2} \left[M(f - f_c) + M(f + f_c) \right] + \frac{a_2 A_c^2 K_a^2}{4} \left[M(f - 2f_c) + M(f + 2f_c) \right]$$

$$+ \frac{a_2 A_c^2 K_a^2}{2} \left[M(f) \atop {\pm 2W} \right] + \frac{a_2 A_c^2 K_a^2}{2} \left[M(f - 2f_c) + M(f + 2f_c) \right]$$

$$+ \frac{a_2 A_c^2}{4} \left[\delta(f - 2f_c) + \delta(f + 2f_c) \right] + a_2 A_c^2 K_a \left[M(f) \right]$$

The device output consists of a dc component at f =0, information signal ranging from 0-W Hz and its second harmonics and frequency bands centered at fc and 2fc. The required information can be separated using low pass filter with cut off frequency ranging between W and fc-w. The filter output is given by

$$m'(t) = \left(a_o + \frac{a_2 A_c^2}{2} \right) + a_2 A_c^2 K_a m(t) + \frac{a_2 A_c^2 K_a^2 m^2(t)}{2}$$

DC component + message signal + second harmonic

The dc component (first term) can be eliminated using a coupling capacitor or a transformer. The effect of second harmonics of information signal can be reduced by maintaining its level very low. When *m(t)* is very low, the filter output is given by

$$m^1(t) = a_2 A_c^2 K_a m(t)$$

When the information level is very low, the noise effect increases at the receiver, hence the system clarity is very low using square law demodulator.

EnvelopeDetector

Itisasimpleand highlyeffectivesystem. This method isused in mostofthecommercialAM radio receivers. An envelope detector is as shown below.
Fig.7.EnvelopeDetector

During the positive half cycles of the input signals, the diode D is forward biased and the capacitor C charges up rapidly to the peak of the input signal. When the input signal falls below this value, the diode becomes reverse biased and the capacitor C discharges through the load resistor RL.

The discharge process continues until the next positive half cycle. When the input signalbecomesgreaterthanthe voltage acrossthe capacitor,the diode conductsagainand the process is repeated.

The charge time constant (rf+Rs)C must be short compared with the carrier period,the capacitor charges rapidlyand there by follows the applied voltage up to the positive peak when the diode is conducting.That is the charging time constant shall satisfythe condition,

$$\left(r_f + R_s\right)C << \frac{1}{f_c}$$

On the other hand, the discharging time-constant $R_L C$ must be long enough to ensure that the capacitor discharges slowly through the load resistor R_L between the positive peaks of the carrier wave, but not so long that the capacitor voltage will not discharge at the maximum rate of change of the modulating wave.

That is the discharge time constant shall satisfy the condition,

$$\frac{1}{f_c} << R_L C << \frac{1}{W}$$

Where'W'isbandwidthofthemessagesignal.Theresultisthatthecapacitorvoltageordetectoroutput isnearlythesameasthe envelope of AM wave.

AdvantagesandDisadvantagesofAM:

Advantages of AM:

- Generation and demodulation of AM wave are easy.
- AM systems are cost effective and easy to build.

Disadvantages:
- AM contains unwanted carrier component, hence it requires more transmission power.
- The transmission bandwidth is equal to twice the message bandwidth.

To overcome these limitations, the conventional AM system is modified at the cost of increased system complexity. Therefore, three types of modified AM systems are discussed.

DSBSC(DoubleSideBandSuppressedCarrier)modulation: In DSBC modulation, the modulated wave consists of only the upper and lower side bands. Transmitted power is saved through the suppression of the carrier wave, but the channel bandwidth requirement is the same as before.

SSBSC (Single Side Band Suppressed Carrier) modulation: The SSBSC modulated wave consists of only the upper side band or lower side band. SSBSC is suited for transmission of voice signals. It is an optimum form of modulation in that it requires the minimum transmission power and minimum channel band width. Disadvantage is increased cost and complexity.

VSB (VestigialSideBand)modulation: In VSB, one side band is completely passed and just a trace or vestige of the other side band is retained. The required channel bandwidth is therefore in excess of the message bandwidth by an amount equal to the width of the vestigial side band. This method is suitable for the transmission of wide band signals.

DSB-SCMODULATION

DSB-SCTimedomain andFrequencydomainDescription:

DSBSC modulators make use of the multiplying action in which the modulating signal multiplies the carrier wave. In this system, the carrier component is eliminated and bothupperandlowerside bandsaretransmitted.Asthecarriercomponent issuppressed,the power required for transmission is less than that of AM.

If $m(t)$ is the message signal and $c(t) = A_c \cos(2\pi f_c t)$ is the carrier signal, then DSBSC modulated wave $s(t)$ is given by

$$s(t) = c(t)\, m(t)$$

$$s(t) = A_c \cos(2\pi f_c t) m(t)$$

Consequently,the modulatedsignals(t)undergoesaphasereversal,wheneverthe message signal m(t) crosses zero as shown below.
Fig.1.(a)DSB-SCwaveform(b)DSB-SCFrequencySpectrum

TheenvelopeofaDSBSC modulatedsignalisthereforedifferent fromthe message signal and the Fourier transform of s(t) is given by

$$S(f) = \frac{A_c}{2}[M(f - f_c) + M(f + f_c)]$$

For the case when base band signal $m(t)$ is limited to the interval $-W<f<W$ as shown in figure below, we find that the spectrum $S(f)$ of the DSBSC wave $s(t)$ is as illustrated below. Except for a change in scaling factor, the modulation process simply translates the spectrum of the base band signal by f_c. The transmission bandwidth required by DSBSC modulation is the same as that for AM.

Figure: Message and the corresponding DSBSC spectrum

GenerationofDSBSC Waves:

BalancedModulator(Product Modulator)

Abalancedmodulatorconsistsoftwostandardamplitudemodulatorsarrangedin abalancedconfigurationsoastosuppressthecarrierwaveasshowninthefollowing block diagram. It is assumed that the AM modulators are identical, except for the signreversalofthemodulatingwaveappliedtotheinputofoneofthem.Thus,theoutputof the two modulators may be expressed as,

$$s_1(t) = A_c[1 + k_a m(t)]\cos(2\pi f_c t)$$
$$s_2(t) = A_c[1 - k_a m(t)]\cos(2\pi f_c t)$$

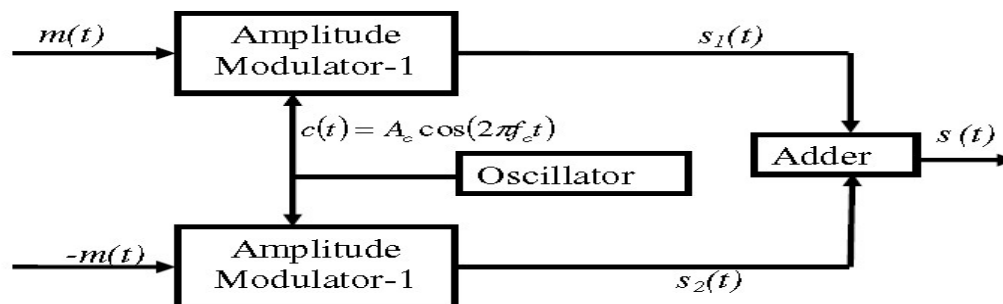

Fig .3 : Balanced modulator

Subtracting $s_2(t)$ from $s_1(t)$,

$$s(t) = s_1(t) - s_2(t)$$
$$s(t) = 2k_a m(t)A_c \cos(2\pi f_c t)$$

Hence,exceptforthescalingfactor2ka,thebalancedmodulatoroutputisequalto the product of the modulating wave and the carrier.

RingModulator

Ring modulator is the most widely used product modulator for generating DSBSC wave and is shown below.

Fig.4 : Ring modulator

Thefourdiodesformaringinwhichtheyallpointinthesamedirection.The diodes are controlled by square wave carrier c(t) of frequency fc, which is applied longitudinallybymeansoftwocenter-tappedtransformers.Assumingthediodesare ideal,whenthecarrierispositive,theouterdiodesD1andD2areforwardbiasedwhere astheinnerdiodesD3andD4arereversebiased,sothatthemodulatormultipliesthe basebandsignalm(t)byc(t).Whenthecarrierisnegative,thediodesD1andD2are reversebiasedandD3andD4areforward,andthemodulatormultipliesthebaseband signal –m(t) by c(t).

Thustheringmodulatorinitsidealformisaproductmodulatorfor squarewavecarrierandthebasebandsignalm(t).Thesquarewavecarriercanbe expanded using Fourier series as

$$c(t) = \frac{4}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{2n-1} \cos(2\pi f_c t(2n-1))$$

Therefore the ring modulator out put is given by

$$s(t) = m(t)c(t)$$

$$s(t) = m(t)\left[\frac{4}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{2n-1} \cos(2\pi f_c t(2n-1))\right]$$

Fromtheaboveequationitisclearthatoutputfromthemodulatorconsists entirelyofmodulationproducts.Ifthemessagesignalm(t)isbandlimitedtothe frequency band − w < f < w, the output spectrumconsists of side bands centred at fc.

DetectionofDSB-SCwaves:

CoherentDetection:

Themessagesignalm(t)canbeuniquelyrecoveredfromaDSBSCwaves(t)by   first multiplying s(t) with a locally generated sinusoidal wave and then low pass filtering the product as shown.

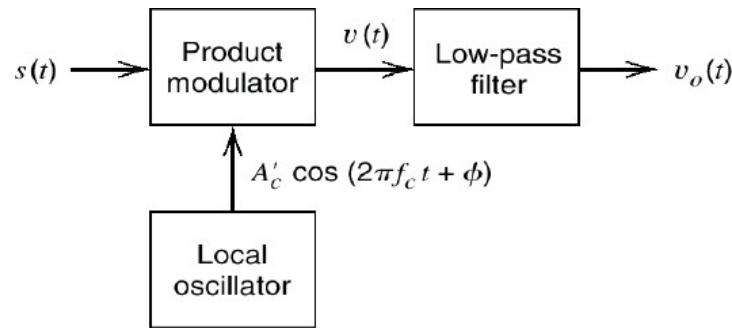

Fig.5 : Coherent detector

It is assumed that the local oscillator signal is exactly coherent or synchronized, in both frequency and phase, with the carrier wave c(t) used in the product modulator togenerates(t).Thismethodofdemodulationisknownascoherentdetectionor   synchronous detection.

Let $A_c^1 \cos(2\pi f_c t + \phi)$ be the local oscillator signal, and $s(t) = A_c \cos(2\pi f_c t) m(t)$ be the DSBSC wave. Then the product modulator output $v(t)$ is given by

$$v(t) = A_c A_c^1 \cos(2\pi f_c t)\cos(2\pi f_c t + \phi)m(t)$$

$$v(t) = \frac{A_c A_c^1}{4}\cos(4\pi f_c t + \phi)m(t) + \frac{A_c A_c^1}{2}\cos(\phi)m(t)$$

The first term in the above expression represents a DSBSC modulated signal with a carrier frequency $2f_c$, and the second term represents the scaled version of message signal. Assuming that the message signal is band limited to the interval $-w < f < w$, the spectrum of $v(t)$ is plotted as shown below.

Fig.6.Spectrumofoutput oftheproductmodulator

From the spectrum, it is clear that the unwanted component (first term in the expression)canberemovedbythelow-passfilter,providedthatthecut-offfrequencyof the filter is greater than W but less than 2fc-W. The filter output is given by

$$v_o(t) = \frac{A_c A_c^1}{2} \cos(\phi)m(t)$$

Thedemodulatedsignalv$_o$(t)isthereforeproportionaltom(t) whenthephaseerrorϕ isconstant.

CostasReceiver(CostasLoop):

Costasreceiver isasynchronousreceiversystem,suitablefordemodulatingDSBSC waves. It consists of two coherent detectors supplied with the same input signal,

that is the incoming DSBSC wave $s(t) = A_c \cos(2\pi f_c t)m(t)$ but with individual local oscillator signals that are in phase quadrature with respect to each other as shown below.

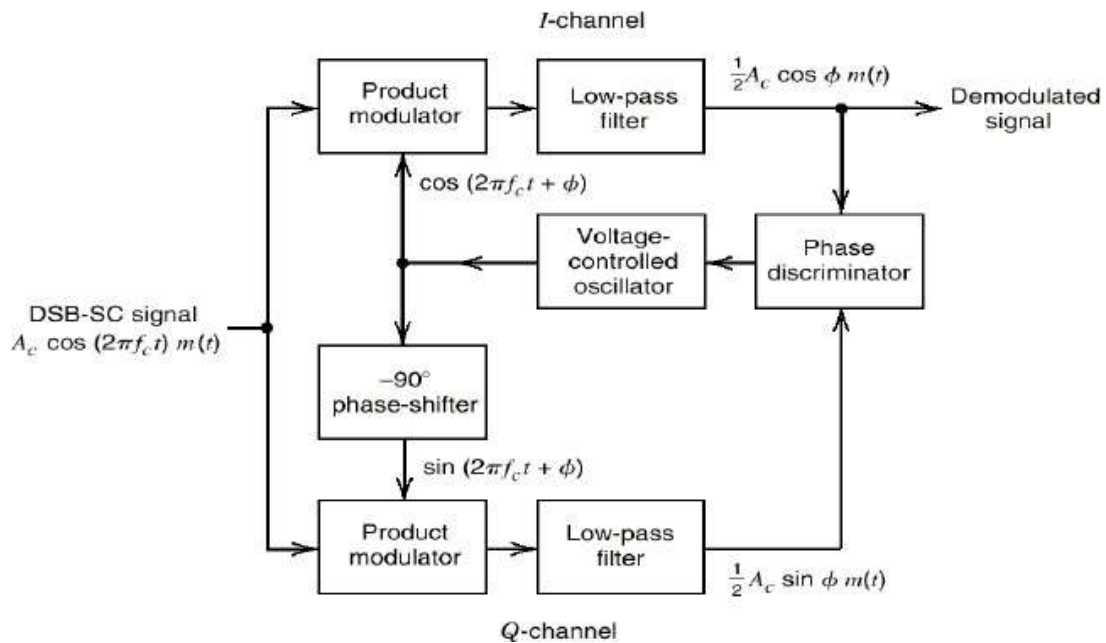

Fig.7.CostasReceiver

The frequency of the local oscillator is adjusted to be the same as the carrierfrequencyfc. The detector inthe upper pathis referredto asthe in-phase coherent detector or I-channel, and thatin the lower path is referred to as the quadrature-phase coherent detector or Q-channel.

These two detector are coupled together to forma negative feedback systemdesigned insuchawayastomaintainthelocaloscillatorsynchronouswiththecarrierwave.Suppose

thelocaloscillatorsignalisofthesamephaseasthecarrier $c(t) = A_c\cos(2\pi f_c t)$ wave used to generate the incoming DSBSC wave. Then we find thattheI-channel output contains the desired demodulated signal m(t), where asthe Q-channeloutputiszeroduetoquadraturenulleffectoftheQ-channel.Supposethatthe local oscillator phase drifts from its proper value by a small angle ϕ radians. The I-channel outputwillremainessentiallyunchanged,buttherewillbesomesignal appearingattheQ-channeloutput,whichisproportionalto $\sin(\phi) \approx \phi$ for small ϕ.

This Q-channel output will have same polarity as the I-channel output for one directionoflocaloscillator phasedrift and oppositepolarityfortheoppositedirectionoflocal oscillator phase drift. Thus by combining the I-channel and Q-channel outputs in a phase discriminator (which consists of a multiplier followed by a LPF), a dc control signal is obtained that automatically corrects for the local phase errors in the voltage-controlled oscillator.

RadioTransmitters

There are two approaches in generating an AM signal. These are known as low and high level modulation. They're easy to identify: A low level AM transmitter performs the processofmodulationnearthebeginningofthetransmitter. Ahighleveltransmitterperforms the modulation step last, at the last or "final" amplifier stage in the transmitter. Each method has advantages and disadvantages, and both are in common use.
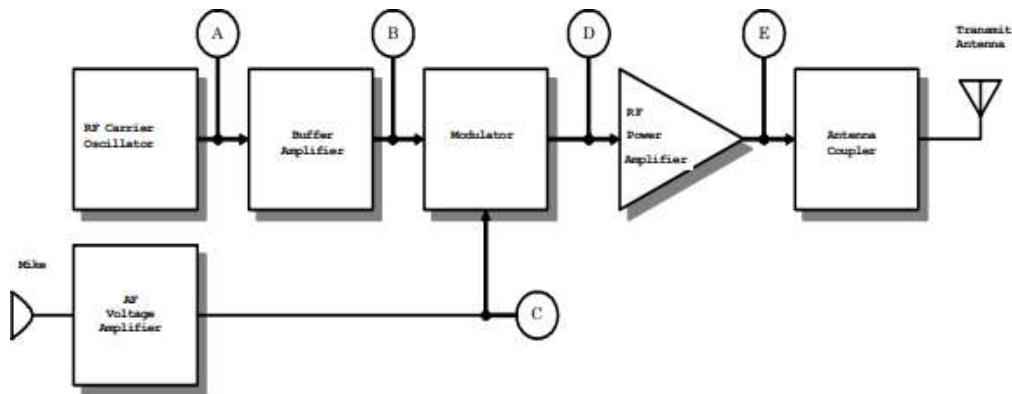

Low-LevelAMTransmitter:

Fig.8.Low-LevelAMTransmitterBlock Diagram

There are two signal paths in the transmitter, audio frequency (AF) and radio frequency (RF). The RF signal is created in the RF carrier oscillator. At test point A the oscillator's output signal is present. The output of the carrier oscillator is a fairly small AC voltage, perhaps 200 to 400 mV RMS. The oscillator is a critical stage in any transmitter. It must produce an accurate and steady frequency. Every radio station is assigned a different carrierfrequency.Thedial(ordisplay)ofareceiverdisplaysthecarrierfrequency.Ifthe

oscillator drifts off frequency, the receiver will be unable to receive the transmitted signal without being readjusted. Worse yet, if the oscillator drifts onto the frequency being used by another radio station, interference will occur. Two circuit techniques are commonly used to stabilize the oscillator, buffering and voltage regulation.

The buffer amplifier has something to do with buffering or protecting the oscillator. An oscillator is a little like an engine (with the speed of the engine being similar to the oscillator's frequency). If the load on the engine is increased (the engine is asked to do more work), the engine will respond by slowing down. An oscillator acts in a very similar fashion. If the current drawn from the oscillator's output is increased or decreased, the oscillator may speed up or slow down slightly.

Buffer amplifier is a relatively low-gain amplifier that follows the oscillator. It has a constant input impedance (resistance). Therefore, it alwaysdrawsthe same amount ofcurrent from the oscillator. This helps to prevent "pulling" of the oscillator frequency. The buffer amplifier is needed because of what's happening "downstream" of the oscillator. Right after this stage is the modulator. Because the modulator is a nonlinear amplifier, it may not have a constant input resistance -- especiallywhen information ispassing into it. But since there isa buffer amplifier between the oscillator and modulator, the oscillator sees a steady load resistance, regardless of what the modulator stage is doing.

Voltage Regulation: An oscillator can also be pulled off frequency if its powersupply voltage isn't held constant. In most transmitters, the supply voltage to the oscillator is regulated at a constant value. The regulated voltage value is often between 5 and 9 volts; zener diodes and three-terminalregulator ICs are commonly used voltage regulators. Voltage regulation is especially important when a transmitter is being powered by batteries or an automobile's electrical system. As a battery discharges, its terminal voltage falls. The DC supply voltage in a car can be anywhere between 12 and 16 volts, depending on engine RPM and other electrical load conditions within the vehicle.

Modulator: The stabilized RF carrier signal feeds one input of the modulator stage. The modulator is a variable-gain (nonlinear) amplifier. To work, it must have an RF carrier signal and an AF information signal. In a low-level transmitter, the power levels are low in the oscillator, buffer, and modulator stages; typically, the modulatoroutput is around 10 mW (700 mV RMS into 50 ohms) or less.

AF Voltage Amplifier: In order for the modulator to function, it needs aninformation signal. A microphone is one wayofdeveloping the intelligence signal, however, it onlyproduces a few millivolts ofsignal. This simplyisn't enoughtooperatethe modulator, so a voltage amplifier is used to boost the microphone's signal. The signal levelat the output of the AF voltage amplifier is usually at least 1 volt RMS; it is highly dependent upon the transmitter's design. Notice that the AF amplifier in the transmitter isonly providing a voltage gain, and not necessarilya current gain forthe microphone'ssignal. The power levels are quite small at the output of this amplifier; a few mW at best.

RF Power Amplifier: At test point D the modulator has created an AM signal by impressing the informationsignalfromtest point Contothe stabilized carrier signalfromtest point B at the buffer amplifier output. This signal (test point D) is a complete AM signal, but has only a few milliwatts of power. The RF power amplifier is normally built with several stages. These stages increase both the voltage and current of the AM signal. We say that power amplification occurs when a circuit provides a current gain. In order to accurately amplify the tiny AM signal from the modulator, the RF power amplifier stages must belinear. You might recall that amplifiers are divided up into "classes," according to the conductionangleoftheactivedevicewithin. Class Aand classBamplifiersareconsidered to be linear amplifiers, so the RFpower amplifier stages will normally be constructed using one or both of these type of amplifiers. Therefore, the signal at test point E looks just like that of test point D; it's just much bigger in voltage and current.

Antenna Coupler: The antenna coupler is usually part of the last or final RF power amplifier, and as such, is not really a separate active stage. It performs no amplification, and has no active devices. It performs two important jobs: Impedance matching and filtering. For an RF power amplifier to function correctly, it must be supplied with a load resistance equal to that for which it was designed.

The antenna coupler also actsasa low-pass filter. This filtering reducesthe amplitude of harmonic energies that may be present in the power amplifier's output. (All amplifiers generate harmonic distortion, even "linear" ones.) For example, the transmitter may be tuned to operate on 1000 kHz. Because of small nonlinearities in the amplifiers of the transmitter, the transmitter will also produce harmonic energies on 2000 kHz (2nd harmonic), 3000 kHz (3rd harmonic), and so on. Because a low-pass filter passes the fundamentalfrequency(1000 kHz) and rejects the harmonics, we say that harmonic attenuation has taken place.
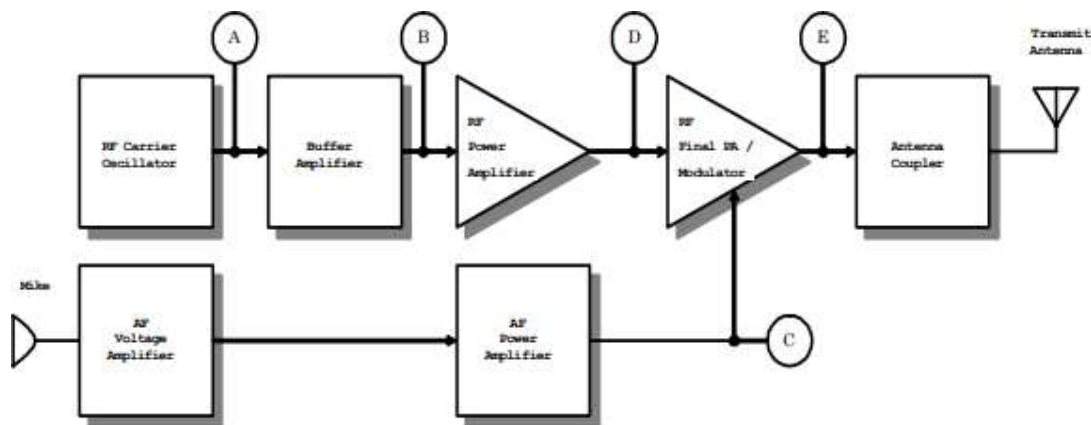

High-LevelAMTransmitter:

Fig.9.Low-LevelAMTransmitterBlock Diagram

The high-level transmitter of Figure 9 is very similar to the low-level unit. The RF section begins just like the low-level transmitter; there is an oscillator and buffer amplifier. Thedifferenceinthehighleveltransmitteriswherethemodulationtakesplace.Insteadof

adding modulation immediately after buffering, this type of transmitter amplifies the unmodulated RF carrier signal first. Thus, the signals at points A, B, and D in Figure 9 all look like unmodulated RF carrier waves. The only difference is that they become bigger in voltage and current as they approach test point D.

The modulation process in a high-level transmitter takes place in the last or final power amplifier. Because of this, an additional audio amplifier section is needed. In order to modulate an amplifier that is running at power levels of several watts (or more), comparable power levels of information are required. Thus, an audio power amplifier is required. The final power amplifier does double-duty in a high-level transmitter. First, it provides power gain for the RF carrier signal, just like the RF power amplifier did in the low-leveltransmitter. In addition to providing power gain, the final PA also performs the task of modulation. The finalpower amplifier in a high-level transmitter usually operates in class C, which is a highly nonlinear amplifier class.

Comparison:

LowLevelTransmitters

- Canproduceanykindofmodulation; AM,FM,orPM.
- RequirelinearRFpoweramplifiers,whichreduceDCefficiencyandincreases production costs.

HighLevelTransmitters

- HavebetterDCefficiency thanlow-leveltransmitters,andarevery wellsuitedfor battery operation.
- Arerestrictedtogenerating AMmodulationonly.

UNIT-II

IntroductionofSSB-SC

Standard AM and DSBSC require transmission bandwidth equalto twice the message bandwidth.InboththecasesspectrumcontainstwosidebandsofwidthWHz, each.Buttheupperandlowersidesareuniquelyrelatedtoeachotherbythevirtueof theirsymmetryaboutthecarrierfrequency.Thatis,giventheamplitudeandphase spectraofeithersideband,theothercanbeuniquelydetermined.Thusifonlyoneside   band   is transmitted, and if both the carrier and the other side band are suppressed at the transmitter, no information is lost. This kind of modulation is called SSBSC and spectral comparison between DSBSC and SSBSC is shown in the figures 1 and 2.

Figure.1   : Spectrum of the DSBSC wave

Figure .2 : Spectrum of the SSBSC wave

FrequencyDomainDescription

Consider a message signal $m(t)$ with a spectrum $M(f)$ band limited to the interval $-w < f < w$ as shown in figure 3   , the DSBSC wave obtained by multiplexing $m(t)$ by the carrier wave $c(t) = A_c \cos(2\pi f_c t)$ and is also shown, in figure 4   . The upper side band is represented in duplicate by the frequencies above f_c and those below $-f_c$, and when only upper

sidebandistransmitted;theresultingSSBmodulatedwavehasthespectrumshowninfigure 6.Similarly,thelowersidebandisrepresentedinduplicatebythefrequencies belowfcandthoseabove-fcandwhenonlythelowersidebandistransmitted,the spectrumofthecorrespondingSSBmodulatedwaveshowninfigure5.Thustheessentialfunction of theSSBmodulationisto translatethespectrum of themodulating wave,eitherwithorwithoutinversion,toanewlocationinthefrequencydomain. TheadvantageofSSBmodulationisreducedbandwidthandtheeliminationof high power carrier wave. The main disadvantage is the cost and complexity of its implementation.

GenerationofSSBwave:

Frequencydiscriminationmethod

Consider the generation of SSB modulated signal containing the upper side bandonly.Fromapracticalpointofview,themostsevererequirementofSSBgeneration arises from the unwanted sideband, the nearest component of which is separated from the desiredsidebandbytwicethelowestfrequencycomponentofthemessagesignal.It impliesthat,forthegenerationofanSSBwavetobepossible,themessagespectrum musthaveanenergygapcenteredattheoriginasshowninfigure7.Thisrequirement is naturally satisfied by voice signals, whose energy gap is about 600Hz wide.
Figure .7   : Message spectrum with energy gap at the origin

Thefrequency discrimination or filtermethod of SSB generation consists of aproduct modulator, which produces DSBSC signal and a band-pass filter to extract thedesired side band and reject the other and is shown in the figure 8.

Figure .8   : Frequency discriminator to generate SSBSC wave

Applicationofthismethodrequiresthatthemessagesignalsatisfiestwoconditions:
1. Themessagesignalm(t)hasnolow-frequencycontent.Example:speech,audio,music.
2. ThehighestfrequencycomponentWofthemessagesignalm(t)ismuchlessthanthe carrier frequency fc.

Then, under these conditions, the desired side band will appear in a non-overlapping interval in the spectrum in such a waythat it may be selected byan appropriate filter.

Indesigningthebandpassfilter,thefollowingrequirementsshouldbesatisfied:
    1.Thepass band ofthe filter occupiesthesame frequencyrangeasthe spectrumofthe desired SSB modulated wave.

2. The width of the guard band of the filter, separating the pass band from the stop band, where the unwanted sideband of the filter input lies, is twice the lowest frequency component of the message signal.

Whenit isnecessaryto generateanSSB modulatedwaveoccupyinga frequency band that is much higher than that of the message signal, it becomes very difficult to design an appropriate filter that will pass the desired side band and reject the other. Insuch a situationitisnecessarytoresorttoamultiple-modulationprocesssoastoeasethefiltering

requirement. This approach is illustrated in the following figure 9 involving two stages of modulation.

Figure .9 : Two stage frequency discriminator

TheSSBmodulatedwaveatthefirstfilteroutputisusedasthemodulatingwave for the second product modulator, which produces a DSBSC modulated wave with a spectrumthatissymmetricallyspacedaboutthesecondcarrierfrequencyf2.The frequencyseparationbetweenthesidebandsofthisDSBSCmodulatedwaveis effectively twicethefirstcarrierfrequency f1,thereby permittingthesecondfilterto remove the unwanted side band.

HilbertTransform&itsProperties:

TheFourier transformisuseful for evaluating the frequencycontent ofanenergysignal, or in a limiting case that of a power signal. It provides mathematical basis for analyzing and designing the frequency selective filters for the separation of signals on the basis of their frequency content.Another method of separating the signals is based on phase selectivity, whichusesphaseshiftsbetweentheappropriatesignals(components) to achieve the desired separation. In case of a sinusoidal signal, the simplest phase shift of 180° is obtained by "Ideal transformer" (polarity reversal). When the phase angles of all the components of a given signalareshifted by90°, theresulting functionoftime iscalled the "Hilbert transform"ofthe signal. ConsideranLTIsystemwithtransferfunctiondefinedbyequation1

$$H(f) = \begin{cases} -j, f > 0 \\ 0, f = 0 \\ j, f < 0 \end{cases} \qquad \text{---------------- (1)}$$

and the Signum function given by
$$\text{sgn}(f) = \begin{cases} 1, f > 0 \\ 0, f = 0 \\ -1, f < 0 \end{cases}$$

The function $H(f)$ can be expressed using Signum function as given by 2

$$H(f) = -j\,\text{sgn}(f) \qquad \text{-------------------- (2)}$$

We know that $1e^{-j\pi/2} = -j$, $1e^{j\pi/2} = j$ and $e^{\pm j\theta} = \cos(\theta) \pm j\sin(\theta)$

Therefore,

$$H(f) = \begin{cases} 1e^{-j\pi/2}, f > 0 \\ 1e^{j\pi/2}, f < 0 \end{cases}$$

Thus the magnitude $|H(f)| = 1$, for all f, and angle

$$\angle H(f) = \begin{cases} -\pi/2, f > 0 \\ +\pi/2, f < 0 \end{cases}$$

The device whichpossessessucha propertyiscalled Hilbert transformer. Whenever a signalisapplied tothe Hilbert transformer,the amplitudesofall frequencycomponentsofthe input signal remain unaffected. It produces a phase shift of -90° for all positive frequencies, while a phase shifts of 90° for all negative frequencies of the signal.

Ifx(t)is an input signal, then its Hilbert transformer is denoted byxˆ(t)and shown in the following diagram.

$$x(t) \longrightarrow \boxed{\text{Hilbert Transformer}} \longrightarrow \hat{x}(t)$$
To find impulse response *h(t)* of Hilbert transformer with transfer function *H(f)*.

Consider the relation between Signum function and the unit step function.

$$\text{sgn}(t) = 2u(t) - 1 = x(t),$$

Differentiating both sides with respect to t,

$$\frac{d}{dt}\{x(t)\} = 2\delta(t)$$

Apply Fourier transform on both sides,

$$\text{sgn}(t) \leftrightarrow \frac{2}{j\omega} \longrightarrow \text{sgn}(t) \leftrightarrow \frac{1}{j\pi f}$$

Applying duality property of Fourier transform,

$$-Sgn(f) \leftrightarrow \frac{1}{j\pi t}$$

We have $\qquad H(f) = -j\,\mathrm{sgn}(f)$

$$H(f) \leftrightarrow \frac{1}{\pi t}$$

Therefore the impulse response *h(t)* of an Hilbert transformer is given by the equation 3 ,

$$\boxed{h(t) = \frac{1}{\pi t}} \qquad \text{------------------ (3)}$$

Now consider any input x(t) to the Hilbert transformer, which is an LTI system. Let the impulse response of the Hilbert transformer is obtained by convolving the input x(t) and impulse response h(t) of the system.

$$\hat{x}(t) = x(t) * h(t)$$

$$\hat{x}(t) = x(t) * \frac{1}{\pi t}$$

$$\boxed{\hat{x}(t) = \frac{1}{\pi} \int_{-\infty}^{+\infty} \frac{x(\tau)}{(t-\tau)} d\tau} \qquad \text{------------------ (4)}$$

The equation 3.5 gives the Hilbert transform of *x(t)*.

The inverse Hilbert transform *x(t)* is given by

$$\boxed{x(t) = \frac{-1}{\pi} \int_{-\infty}^{+\infty} \frac{\hat{x}(\tau)}{(t-\tau)} d\tau} \qquad \text{------------------ (5)}$$

We have $\qquad \hat{x}(t) = x(t) * h(t)$

The Fourier transform $\hat{X}(f)$ of $\hat{x}(t)$ is given by

$$\hat{X}(f) = X(f) H(f)$$

$$\hat{X}(f) = -j\,\mathrm{sgn}(f) X(f) \qquad \text{------------------ (6)}$$

Properties:

1. "A signal $x(t)$ and its Hilbert transform $\hat{x}(t)$ have the same amplitude spectrum".

The magnitude of $-jsgn(f)$ is equal to 1 for all frequencies f. Therefore $x(t)$ and $\hat{x}(t)$ have the same amplitude spectrum.

That is $$\left|\hat{X}(f)\right| = \left|X(f)\right| \qquad \text{for all } f$$

2. "If $\hat{x}(t)$ is the Hilbert transform of $x(t)$, then the Hilbert transform of $\hat{x}(t)$, is $-x(t)$".

To obtain its Hilbert transform of $x(t)$, $x(t)$ is passed through a LTI system with a transfer function equal to $-jsgn(f)$. A double Hilbert transformation is equivalent to passing $x(t)$ through a cascade of two such devices. The overall transfer function of such a cascade is equal to

$$\left[- j\,\mathrm{sgn}(f)\right]^2 = -1 \quad \text{for all } f$$

The resulting output is $-x(t)$. That is the Hilbert transform of $\hat{x}(t)$ is equal to $-x(t)$.

TimeDomainDescription:

The time domaindescriptionofanSSBwave s(t) inthe canonicalformisgiven by the equation 1.

$$s(t) = s_I(t)\cos(2\pi f_c t) - s_Q(t)\sin(2\pi f_c t) \quad \text{-------------------} (\,1\,)$$

where $S_I(t)$ is the in-phase component of the SSB wave and $S_Q(t)$ is its quadrature component. The in-phase component $S_I(t)$ except for a scaling factor, may be derived from $S(t)$ by first multiplying $S(t)$ by $\cos(2\pi f_c t)$ and then passing the product through a low-pass filter. Similarly, the quadrature component $S_Q(t)$, except for a scaling factor, may be derived from $s(t)$ by first multiplying $s(t)$ by $\sin(2\pi f_c t)$ and then passing the product through an identical filter.

The Fourier transformation of $S_I(t)$ and $S_Q(t)$ are related to that of SSB wave as follows, respectively.

$$S_I(f) = \begin{cases} S(f - f_c) + S(f + f_c), & -w \le f \le w \\ 0, & elsewhere \end{cases} \quad \text{-------------------} (\,2\,)$$

$$S_Q(f) = \begin{cases} j[S(f - f_c) - S(f + f_c)], & -w \leq f \leq w \\ 0, \, elsewhere \end{cases}$$ ------------------ (3)

where $-w < f < w$ defines the frequency band occupied by the message signal *m(t)*.

Consider the SSB wave that is obtained by transmitting only the upper side band, shown in figure 10 . Two frequency shifted spectra $S(f - f_c)$ and $S(f + f_c)$ are shown in figure 11 and figure 12 respectively. Therefore, from equations 2 and 3 , it follows that the corresponding spectra of the in- phase component $S_I(t)$ and the quadrature component $S_Q(t)$ are as shown in figure 13 and 14 respectively.

Figure 10 : Spectrum of SSBSC-USB

Figure 11 : Spectrum of SSBSC-USB shifted right by f_c

Figure 12 : Spectrum of SSBSC-USB shifted left by f_c
Figure 13 : Spectrum of in-phase component of SSBSC-USB
Figure 14 : Spectrum of quadrature component of SSBSC-USB

From the figure 13 , it is found that

$$S_I(f) = \frac{1}{2} A_c M(f)$$

where $M(f)$ is the Fourier transform of the message signal $m(t)$. Accordingly in-phase component $S_I(t)$ is defined by equation 4

$$s_I(t) = \frac{1}{2} A_c m(t) \qquad \text{----------------- (4)}$$

Now on the basis of figure14 , it is found that

$$S_Q(f) = \begin{cases} \dfrac{-j}{2} A_c M(f), f > 0 \\ 0, f = 0 \\ \dfrac{j}{2} A_c M(f), f < 0 \end{cases}$$

$$S_Q(f) = \frac{-j}{2} A_c \, \text{sgn}(f) M(f) \qquad \text{----------------- (5)}$$

where $\text{sgn}(f)$ is the Signum function.

But from the discussions on Hilbert transforms, it is shown that

$$-j\,\mathrm{sgn}(f)M(f)=\hat{M}(f) \qquad \text{-----------------} (6)$$

where $\hat{M}(f)$ is the Fourier transform of the Hilbert transform of $m(t)$. Hence the substituting equation (6) in (5), we get

$$S_Q(f)=\frac{1}{2}A_c\hat{M}(f) \qquad \text{-----------------------} (7)$$

Therefore quadrature component $s_Q(t)$ is defined by equation 8

$$\boxed{s_Q(t)=\frac{1}{2}A_c\hat{m}(t)}$$

$$\text{-------------------------} (8)$$

Therefore substituting equations (4) and (8) in equation in (1), we find that canonical representation of an SSB wave $s(t)$ obtained by transmitting only the upper side band is given by the equation 9

$$\boxed{s_U(t)=\frac{1}{2}A_c m(t)\cos(2\pi f_c t)-\frac{1}{2}A_c\hat{m}(t)\sin(2\pi f_c t)} \quad \text{-------------} (9)$$

Followingthesameprocedure,wecanfindthecanonicalrepresentationforan SSB wave
s(t)obtainedbytransmittingonlythelowersidebandisgivenby

$$s_L(t)=\frac{1}{2}A_c m(t)\cos(2\pi f_c t)+\frac{1}{2}A_c\hat{m}(t)\sin(2\pi f_c t) \qquad \text{--------------} (10)$$

Phasediscriminationmethodforgenerating SSBwave:

Time domain description of SSB modulation leads to another method of SSB generationusingtheequations9or10.Theblockdiagramofphasediscriminatoris   as   shown   in figure 15.

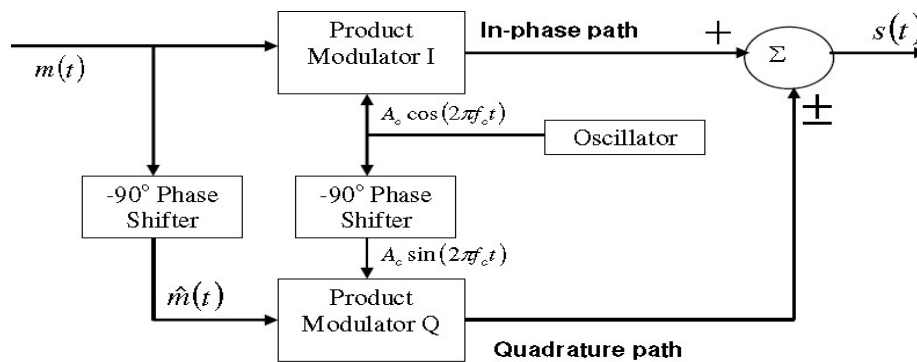

Figure 15 : Block diagram of phase discriminator

The phase discriminator consists of two product modulators I and Q, supplied with carrier waves in-phase quadrature to each other. The incoming baseband signal m(t) is applied to product modulator I, producing a DSBSC modulated wave that contains reference phase sidebands symmetrically spaced about carrier frequency fc.

The Hilbert transform mˆ (t) of m (t) is applied to product modulator Q, producing a DSBSC modulated that contains side bands having identical amplitude spectra to those of modulator I, but with phase spectra such that vector addition or subtraction of the two modulator outputs results in cancellation of one set of sidebands and reinforcement of the other set.

The use of a plus sign at the summing junction yields an SSB wave with only the lower sideband, whereas the use of a minus sign yields an SSB wave with only the upper side band. This modulator circuit is called Hartley modulator.

Demodulation of SSB Waves:

Demodulation of SSBSC wave using coherent detection is as shown in 16 . The SSB wave s(t) together with a locally generated carrier $c(t) = A_c{}' \cos(2\pi f_c t + \phi)$ is applied to a product modulator and then low-pass filtering of the modulator output yields the message signal.
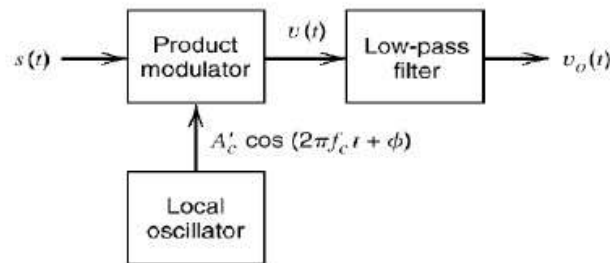

Figure 16 : Block diagram of coherent detector for SSBSC

The product modulator output v(t) is given by

$$v(t) = A_c{}' \cos(2\pi f_c t + \phi) s(t) , \quad \text{Put } \phi = 0$$

$$v(t) = \frac{1}{2} A_c \cos(2\pi f_c t)[m(t)\cos(2\pi f_c t) \pm \hat{m}(t)\sin(2\pi f_c t)]$$

$$v(t) = \frac{1}{4} A_c m(t) + \frac{1}{4} A_c [m(t)\cos(4\pi f_c t) \pm \hat{m}(t)\sin(4\pi f_c t)] \quad ....(1)$$

The first term in the above equation 1 is desired message signal. The other term represents an SSB wave with a carrier frequency of 2fc as such; it is an unwanted component, which is removed by low-pass filter.

IntroductiontoVestigialSideBandModulation

Vestigial sideband is a type of Amplitude modulation in which one side band is completely passed along with trace or tail or vestige of the other side band. VSB is a compromisebetweenSSBandDSBSCmodulation.InSSB,wesendonlyonesideband, the Bandwidth required to send SSB wave is w. SSB is not appropriate way of modulation when the message signal contains significant components at extremely low frequencies. To overcome this VSB is used.

Where f_v is the width of the vestigial side band.

Similarly, if Upper side band is modified into the vestigial side band then,
Fig (d) Spectrum of VSB wave containing vestige of the Upper side band

The vestige of the Upper side band compensates for the amount removed from the Lower side band. The bandwidth required to send VSB wave is B=w+fv, where fv is the width of the vestigial side band.

Therefore, VSB has the virtue of conserving bandwidth almost as efficiently as SSB modulation, while retaining the excellent low-frequency baseband characteristics of DSBSC and it is standard for the transmission of TV signals.

Generation of VSB Modulated Wave

VSB modulated wave is obtained by passing DSBSC through a sideband shaping filter as shown in fig below.
Fig.17.Block Diagram of VSB Modulator

The exact design of this filter depends on the spectrum of the VSB waves. The relation between filter transfer function H (f) and the spectrum of VSB waves is given by

$$S(f)=Ac/2 [M(f-fc)+ M(f+fc)]H(f) \text{ ------------------------------- (1)}$$

Where M(f) is the spectrum of Message Signal. Now, we have to determine the specification for the filter transfer function H(f) It can be obtained by passing s(t) to a

coherent detector and determining the necessary condition for undistorted version of the message signal m(t). Thus, s (t) is multiplied by a locally generated sinusoidal wave cos $(2\pi f_c t)$ which is synchronous with the carrier wave $A_c \cos(2\pi f_c t)$ in both frequency and phase, as in fig below,

s(t) → [Product Modulator] v(t) → $v_o(t)$ → [Low Pass Filtr] →

cos2πf$_c$t ↑
Fig(b). Block diagram of VSB Demodulator

Then,   v(t) = s(t). cos2πf$_c$t--(2)

In frequency domain Eqn (2) becomes,

$V(f) = ½ [S(f - f_c) + S(f + f_c)]$ --(3)

Substitution of Eqn (1) in Eqn (3) gives

$V(f) = ½[A_c /2 [M (f - f_c - f_c) + M(f - f_c + f_c)]H(f - f_c)$

$+ ½[A_c /2 [M (f + f_c - f_c) + M(f + f_c + f_c)]H(f + f_c)$

$V(f) = ½[A_c /2 [M (f -2 f_c) + M(f)]H(f - f_c)$

$+ ½[A_c /2 [M (f) + M(f +2f_c)]H(f + f_c)$

$V(f) = A_c /4 M(f)[H (f - f_c) + H(f + f_c)]$

$+ A_c /4 [M(f -2 f_c) H (f - f_c) + M(f + 2f_c) H(f + f_c)]$ ----------------------------(4)

The spectrum of V(f) as shown in fig below,

Fig ©. Spectrum of the product modulator output v(t)

Pass v(t) to a Low pass filter to eliminate VSB wave corresponding to 2f$_c$.

$V_o(f) = A_c /4 M(f)[H (f - f_c) + H(f + f_c)]$ -------------------------------------(5)

ThespectrumofVo(f)isinfig below,

$V_o(f)$

$A_c /4 \, M(0)[H \, (- f_c) + H(f_c)]$

-w   0   w   f
Fig (d). Spectrum of the demodulated Signal $v_o(t)$.

For a distortion less reproduction of the original signal m(t), $V_o(f)$ to be a scaled version of M(f). Therefore, the transfer function H(f) must satisfy the condition

$$H \, (f - f_c) + H(f + f_c) = 2H(f_c) \text{-------------------(6)}$$

Where $H(f_c)$ is a constant

Since m(t) is a band limited signal, we need to satisfy eqn (6) in the interval   -w≤f≤w. The requirement of eqn (6) is satisfied by using a filter whose transfer function is shown below

H(f)

1.0

0.5

0            $f_c-f_v f_c f_c+f_v f_c+w$ f
Fig (e) Frequency response of sideband shaping filter

Note: H(f) is Shown for positive frequencies only.

The Response is normalized so that H(f) at f_c is 0.5. Inside this interval $f_c-f_v≤f≤f_c+f_v$response exhibits odd symmetry. i.e., Sum of the values of H(f) at any two frequencies equally displaced above and below is Unity.

TimeDomainDescription:

Time domain representation of VSB modulated wave, procedure is similar to SSB Modulated waves. Let s(t) denote a VSB modulated wave and assuming that s(t) containing Upper sideband along with the Vestige of the Lower sideband. VSB modulated wave s(t) is the output from Sideband shaping filter, whose input is DSBSC wave. The filter transfer function H(f) is of the form as in fig below,
Fig (1) H(f) of sideband shaping filter

The DSBSC Modulated wave is

$$S_{DSBSC}(t) = A_c\, m(t)\, \cos 2\pi f_c t \quad \text{--------------------(1)}$$

It is a band pass signal and has in-phase component only. Its low pass complex envelope is given by

$$\tilde{s}_{DSBSC}(t) = A_c m(t) \quad \text{--------------------------------(2)}$$

The VSB modulated wave is a band pass signal.

Let the low pass signal $\tilde{s}(t)$ denote the complex envelope of VSB wave s(t), then

$$s(t) = Re[\tilde{s}(t)\, exp(j2\pi f_c t)] \quad \text{------------------------(3)}$$

To determine $\tilde{s}(t)$ we proceed as follows

1. The side band shaping filter transfer function H(f) is replaced by its equivalent complex low pass transfer function denoted by $\tilde{H}(f)$ as shown in fig below
Fig(2) Lowpassequivalentto H(f)

We may express $\widetilde{H}(f)$ as the difference between two components $\widetilde{Hu}(f)$ and $\widetilde{Hv}(f)$ as

$\widetilde{H}(f) = \widetilde{Hu}(f) - \widetilde{Hv}(f)$ ----------------------------(4)

These two components are considered individually as follows

i). The transfer function $\widetilde{Hu}(f)$ pertains to a complex low pass filter equivalent to a band pass filter design to reject the lower side band completely as

$\widetilde{Hu}(f)$
Fig (3) First component of $\widetilde{H}(f)$

$\widetilde{Hu}(f) = \begin{cases} \frac{1}{2}[1+\text{sgn}(f)], & 0<f<w \\ 0, & \text{otherwise} \end{cases}$ ----------------(5)

ii). The transfer function $\widetilde{Hv}(f)$ accounts for the generation of vestige and removal of a corresponding portion from the upper side band.

$\widetilde{Hv}(f)$

Fig (4) Second component of $\widetilde{H}(f)$

Substitute eqn(5) in eqn (4) we get,

$\widetilde{H}(f) = \begin{cases} \frac{1}{2}[1+\text{sgn}(f) - 2\widetilde{Hv}(f)], & f_v<f<w \\ 0, & \text{otherwise} \end{cases}$ ----------------(6)

The sgn(f) and $\widetilde{Hv}$(f) are both odd functions of frequency, Hence, both they have purely imaginary Inverse Fourier Transform (FT). Accordingly, we may introduce a new transfer function

H_Q(f) = 1/j[sgn(f) - 2$\widetilde{Hv}$(f)]   ------------(7)

It has purely Inverse FT and h_Q(t) denote IFT of H_Q(f)

jH_Q(f)
Fig(5) Transfer function of the filter jH_Q(f)

Rewrite eqn(6) interms of H_Q(f) as

$$\widetilde{H}(f) = \begin{cases} \tfrac{1}{2}\,[1+jH_Q(f)], & f_v < f < w \\ 0, & \text{otherwise} \end{cases} \quad ----------------(8)$$

2. The DSBSC modulated wave is replaced by its complex envelope as
   $\tilde{S}_{DSBSC}$(f) = A_c M(f) -----------------(9)
3. The desired complex envelope $\tilde{s}$(t) is determined by evaluating IFT of the product $\widetilde{H}$(f)$\tilde{S}_{DSBSC}$(f).
   i.e., $\tilde{S}$(f) = $\widetilde{H}$(f)$\tilde{S}_{DSBSC}$(f) -----------------------(10)
   $\tilde{S}$(f) = A_c/2[1+jH_Q(f)] M[f] --------------------------(11)
   Take IFT of eqn(11) we get,
   $\tilde{s}$(t) = A_c/2[m(t) + jm_Q(t)] ----------------------(12)
   Where m_Q(t) is the response produced by passing the message through a low pass filter of impulse response h_Q(t).
   Substitute eqn(12) in eqn(3) and simplify, we get
   S(t) = A_c/2 m(t) cos2πf_ct - A_c/2 m_Q(t) sin2πf_ct --------------------(13)
   Where A_c/2 m(t) ----- In-phase component
          A_c/2 m_Q(t)----- Quadrature component

Note:
1. Ifvestigialsidebandis increasedtofullsideband, VSBbecomesDSCSB,i.e., mQ(t)=0.

2. If vestigial side band is reduced to Zero, VSB becomes SSB.
    i.e., m_Q(t) = $\hat{m}$(t)
    Where $\hat{m}$(t) is the Hilbert transform of m(t).

Similarly If VSB containing a vestige of the Upper sideband, then s(t) is given by

$$S(t) = A_c/2 \, m(t) \cos 2\pi f_c t \; + \; A_c/2 \, m_Q(t) \sin 2\pi f_c t \quad \text{--------------------(14)}$$

Envelopedetection ofa VSBWaveplus Carrier

To make demodulation of VSB wave possible by an envelope detector at the receiving end it is necessary to transmit a sizeable carrier together with the modulated wave. The scaled expression of VSB wave by factor k_a with the carrier component $A_c \cos(2\pi f_c \, t)$ can be given by

$$s(t) = A_c \cos(2\pi f_c \, t) + \frac{A_c}{2} k_a \, m(t) \cos(2\pi f_c \, t)$$

$$- \frac{A_c}{2} k_a \, m_Q(t) \sin(2\pi f_c \, t)$$

$$= A_c\left[1 + \frac{k_a}{2} m(t)\right]\cos(2\pi f_c t) - \frac{A_c \, k_a}{2} m_Q(t)\sin(2\pi f_c t) \quad \text{.................(1)}$$

where k_a is the modulation index; it determines the percentage modulation.

When above signal s(t) is passed through the envelope detector, the detector output is given by,

$$a(t) = A_c\left[\left(1 + \frac{k_a}{2} m(t)\right)^2 + \left(\frac{k_a}{2} m_Q(t)\right)^2\right]^{1/2}$$

$$= A_c\left[1 + \frac{k_a}{2} m(t)\right]\left(1 + \left[\frac{\frac{1}{2} k_a \, m_Q(t)}{1 + \frac{1}{2} k_a \, m(t)}\right]^2\right)^{1/2} \quad \text{.................(2)}$$

The detector output is distorted by the quadrature component $m_Q(t)$ as indicated by equation (2).

Methods to reduce distortion

- Distortion can be reduced by reducing percentage modulation, k_a.
- Distortion can be reduced by reducing $m_Q(t)$ by increasing the width of the vestigial sideband.

ComparisonofAMTechniques:

Sr. No.	Parameter	Standard AM	SSB	DSBSC	VSB
1	Power	High	Less	Medium	Less than DSBSC but greater than SSB
2	Bandwidth	$2 f_m$	f_m	$2 f_m$	$f_m < B_w < 2 f_m$
3	Carrier supression	No	Yes	Yes	No
4	Receiver complexity	Simple	Complex	Complex	Simple
5	Application	Radio communication	Point to point communication preferred for long distance transmission.	Point to point communication	Television broadcasting
6	Modulation type	Non linear	Linear	Linear	Linear
7	Sideband suppression	No	One sided completely	No	One sideband suppressed partly
8	Transmission efficiency	Minimum	Maximum	Moderate	Moderate

ApplicationsofdifferentAM systems:

- AmplitudeModulation:AMradio,Shortwaveradiobroadcast
- DSB-SC:DataModems, ColorTV'scolor signals.
- SSB: Telephone
- VSB:TVpicture signals

InstantaneousFrequency

Thefrequencyofacosinefunction$x(t)$that isgivenby

$$x(t)=\cos(\omega_c t+\theta_0)$$

is equal to $\omega_c$since it is a constant with respect to$t$, and the phase of the cosine is the constantθ_0.The angle of the cosine $\theta(t) = \omega_c t +\theta_0$is a linear relationship with respect to$t$ (a straight line with slope of $\omega_c$and y–intercept of θ_0). However, for other sinusoidal functions, the frequency may itself be a function of time, and therefore, we should notthink in terms of the constant frequency of the sinusoid but in terms of the INSTANTANEOUS frequency of the sinusoid since it is not constant for all$t$.Consider for example the following sinusoid

$$y(t)=\cos[\theta(t)],$$

where $\theta(t)$ is a function of time.The frequency of$y(t)$in this case depends on the function of$\theta(t)$and mayitselfbe a functionoftime. The instantaneous frequencyof$y(t)$ givenabove is defined as

$$\omega_i(t)=\frac{d\theta(t)}{dt}.$$

Asacheckupfor thisdefinition, weknowthat theinstantaneousfrequencyof$x(t)$isequalto its frequencyat alltimes (since the instantaneous frequencyfor that function is constant) and isequaltoω_c.Clearlythissatisfiesthe definition ofthe instantaneousfrequencysince$\theta(t)=\omega_c t+\theta_0$andtherefore$\omega_i(t)=\omega_c$.

Ifweknow theinstantaneousfrequencyofsome sinusoidfrom$-\infty$ to sometime$t$, wecanfind the angle of that sinusoid at time tusing

$$\theta(t) =\int_{-\infty}^{t}\omega_i(\alpha)d\alpha.$$

Changing the angle $\theta(t)$ ofsome sinusoid is the bases for the two types ofangle modulation: Phase and Frequency modulation techniques.

PhaseModulation (PM)

In this type of modulation, the phase of the carrier signal is directly changed by the message signal. The phase modulated signal will have the form

$$g_{PM}(t) = A \cdot \cos\left[\omega_c t + k_p m(t)\right],$$

where A is a constant, ω_c is the carrier frequency, $m(t)$ is the message signal, and k_p is a parameter that specifies how much change in the angle occurs for every unit of change of $m(t)$. The phase and instantaneous frequency of this signal are

$$\theta_{PM}(t) = \omega_c t + k_p m(t),$$

$$\omega_i(t) = \omega_c + k_p \frac{dm(t)}{dt} = \omega_c + k_p m(t).$$

So, the frequency of a PM signal is proportional to the derivative of the message signal.

Frequency Modulation (FM)

This type of modulation changes the frequency of the carrier (not the phase as in PM) directly with the message signal. The FM modulated signal is

$$g_{FM}(t) = A \cdot \cos\left[\omega_c t + k_f \int_{-\infty}^{t} m(\alpha) d\alpha\right],$$

where k_f is a parameter that specifies how much change in the frequency occurs for every unit change of $m(t)$. The phase and instantaneous frequency of this FM are

$$\theta_{FM}(t) = \omega_c t + k_f \int_{-\infty}^{t} m(\alpha) d\alpha,$$

$$\omega_i(t) = \omega_c + k_f \frac{d}{dt}\left[\int_{-\infty}^{t} m(\alpha) d\alpha\right] = \omega_c + k_f m(t).$$

Relation between PM and FM

PM and FM are tightly related to each other. We see from the phase and frequency relations for PM and FM given above that replacing $m(t)$ in the PM signal with $\int_{-\infty}^{t} m(\alpha) d\alpha$ gives an FM signal and replacing $m(t)$ in the FM signal with is $\frac{dm(t)}{dt}$ gives a PM signal. This illustrated in the following block diagrams.

FrequencyModulator(FM)

Diagram: $m(t) \rightarrow \boxed{\displaystyle\int_{-\infty}^{t}(\cdot)d\alpha} \xrightarrow{\displaystyle\int_{-\infty}^{t}m(t)d\alpha} \boxed{\begin{array}{c}\text{Phase}\\\text{Modulator}\\\text{(PM)}\end{array}} \rightarrow g_{FM}(t)$

PhaseModulator(PM)

Diagram: $m(t) \rightarrow \boxed{\dfrac{d(\cdot)}{dt}} \xrightarrow{\dfrac{dm(t)}{dt}} \boxed{\begin{array}{c}\text{Frequency}\\\text{Modulator}\\\text{(FM)}\end{array}} \rightarrow g_{PM}(t)$
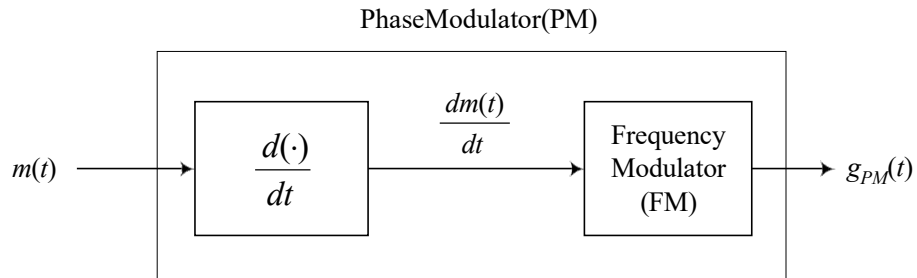

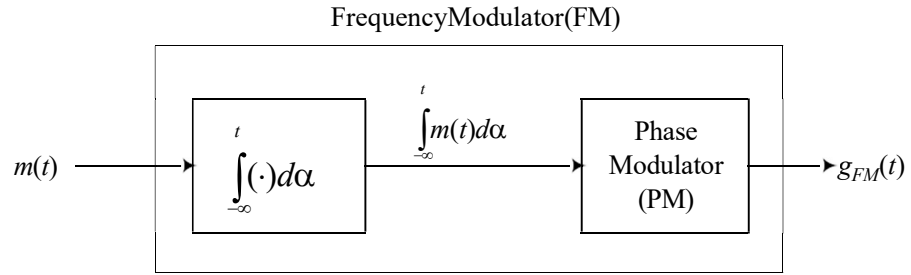

FrequencyModulation

In **F**requency**M**odulation(**FM**)theinstantaneousvalueoftheinformationsignal controls the frequencyof the carrier wave. This is illustrated in the following diagrams.
Notice that as the information signal increases, the frequency ofthe carrier increases, and as the information signal decreases, the frequency of the carrier decreases.

The frequency f_i of the information signal controls the rate at which the carrier frequency increases and decreases. As with AM, f_i must be less than f_c. The amplitude of the carrier remains constant throughout this process.

When the information voltage reaches its maximum value then the change in frequency of the carrier will have also reached its maximum deviation above the nominal value. Similarly when the information reaches a minimum the carrier will be at its lowest frequency below the nominal carrier frequency value. When the information signal is zero, then no deviation of the carrier will occur.

The maximum change that can occur to the carrier from its base value f_c is called the frequency deviation, and is given the symbol Δf_c. This sets the dynamic range (i.e. voltage range) of the transmission. The dynamic range is the ratio of the largest and smallest analogue information signals that can be transmitted.

Bandwidth of FM and PM Signals

The bandwidth of the different AM modulation techniques ranges from the bandwidth of the message signal (for SSB) to twice the bandwidth of the message signal (for DSBSC and FullAM). When FM signals were first proposed, it was thought that their bandwidth can be reduced to an arbitrarily small value. Compared to the bandwidth of different AM modulation techniques, this would in theory be a big advantage. It was assumed that a signal with an instantaneous frequency that changes over of range of Δf Hz would have a bandwidth of Δf Hz. When experiments were done, it was discovered that this was not the case. It was discovered that the bandwidth of FM signals for a specific message signal was at least equal to the bandwidth of the corresponding AM signal. In fact, FM signals can be classified into two types: Narrowband and Wideband FM signals depending on the bandwidth of each of these signals

Narrowband FM and PM

The general form of an FM signal that results when modulating a signals $m(t)$ is

$$g_{FM}(t) = A \cdot \cos\left[\omega_c t + k_f \int_{-\infty}^{t} m(\alpha)\, d\alpha\right].$$

A narrowband FM or PM signal satisfies the condition

$$\left|k_f a(t)\right| \square\ 1$$

For FM and

$$\left|k_p \cdot m(t)\right| \square\ 1$$

For PM, where

$$a(t)=\int_{-\infty}^{t}m(\alpha)d\alpha,$$

suchthatachangeinthemessagesignaldoesnotresultsinalotofchangeinthe instantaneous frequency of the FM signal.

Now,wecanwritetheabove as

$$g_{FM}(t)=A\cdot\cos\left[\omega_c t+k_f a(t)\right].$$

StartingwithFM,toevaluatethebandwidthofthissignal,weneedtoexpanditusinga power series expansion. So, we will define a slightly different signal

$$\hat{g}_{FM}(t)=A\cdot e^{j\{\omega_c t+k_f a(t)\}}=A\cdot e^{j\omega_c t}\cdot e^{jk_f a(t)}.$$

Rememberthat

$$\hat{g}_{FM}(t)=A\cdot e^{j\{\omega_c t+k_f a(t)\}}=A\cdot\cos\left[\omega t+ka(t)_c\right]+jA\cdot\sin\left[\omega t+ka(t)\right],\qquad _c\qquad _f$$

so

$$g_{FM}(t)=\text{Re}\left\{\hat{g}_{FM}(t)\right\}.$$

Nowwecan expandtheterm$e^{jk_f a(t)}$in $\hat{g}_{FM}(t)$, whichgives

$$\hat{g}_{FM}(t)=A\cdot e^{j\omega_c t}\left[1+jka(t)_f+\frac{j^2 k_f^2 a^2(t)}{2!}+\frac{j^3 k_f^3 a^3(t)}{3!}+\frac{j^4 k_f^4 a^4(t)}{4!}+\ \cdots\right]$$

$$=A\cdot\left[e^{j\omega_c t}+jka(t)_f e^{j\omega_c t}-\frac{k_f^2 a^2(t)}{2!}e^{j\omega_c t}-\frac{jk_f^3 a^3(t)}{3!}e^{j\omega_c t}+\frac{k_f^4 a^4(t)}{4!}e^{j\omega_c t}+\ \cdots\right]$$

Since$k_f$and$a(t)$arereal($a(t)$isrealbecause it is theintegralofarealfunction $m(t)$),and since
$$\text{Re}\{e^{j\omega ct}\}=\cos(\omega_c t)\qquad\text{and}\qquad\text{Re}\{je^{j\omega ct}\}=-\sin(\omega_c t),\qquad\text{then}$$

$$g_{FM}(t)=\text{Re}\{\hat{g}_{FM}(t)\}$$

$$=A\cdot\left[\cos(\omega_c t)-k_f a(t)\sin(\omega_c t)-\frac{k_f^2 a^2(t)}{2!}\cos(\omega_c t)+\frac{k_f^3 a^3(t)}{3!}\sin(\omega_c t)+\frac{k_f^4 a^4(t)}{4!}\cos(\omega_c t)+\quad\cdots\right]$$

The assumption we made for narrowband FM is $(\left|k_f a(t)\right|\ll 1)$. This assumption will result in making all the terms with powers of $k_f a(t)$ greater than 1 to be small compared to the first two terms. So, the following is a reasonable approximation for $g_{FM}(t)$

$$\boxed{g_{FM(Narrowband)}(t)\approx A\cdot\left[\cos(\omega_c t)-k_f a(t)\sin(\omega_c t)\right],}$$ when $\left|k_f a(t)\right|\ll 1.$

It must be stressed that the above approximation is only valid for narrowband FM signals that satisfy the condition $(\left|k_f a(t)\right|\ll 1)$. The above signal is simply the addition (or actually the subtraction) of a cosine (the carrier) with a DSBSC signal (but using a sine as the carrier). The message signal that modulates the DSBSC signal is not $m(t)$ but its integration $a(t)$. One of the properties of the Fourier transform informs us that the bandwidth of a signal $m(t)$ and its integration $a(t)$ (and its derivative too) are the same (verify this). Therefore, the bandwidth of the narrowband FM signal is

$$\boxed{BW_{FM(Narrowband)}=BW_{DSBSC}=2\cdot BW_{m(t)}=.}$$

We will see later that when the condition $(k_f\ll 1)$ is not satisfied, the bandwidth of the FM signal becomes higher that twice the bandwidth of the message signal. Similar relationships hold for PM signals. That is

$$\boxed{g_{PM(Narrowband)}(t)\approx A\cdot\left[\cos(\omega_c t)-k_p m(t)\sin(\omega_c t)\right],}$$ when $\left|k_p\cdot m(t)\right|\ll 1,$
and

$$\boxed{BW_{PM(Narrowband)}=BW_{DSBSC}=2\cdot BW_{m(t)}=.}$$

Construction of Narrowband Frequency and Phase Modulators

The above approximations for narrowband FM and PM can be easily used to construct modulators for both types of signals
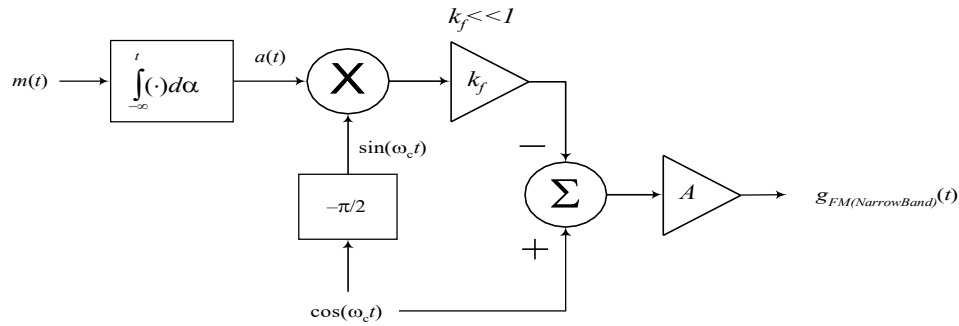

NarrowbandFMModulator

NarrowbandPMModulator

Generation of Wideband FM Signals

Consider the following block diagram

$g_{FM\,(NB)}(t)$

Assume a BPF is included in this block to pass the signal with the highest carrier freuqnecy and reject all others
A narrowband FM signal can be generated easily using the block diagram of the narrowband FM modulator that was described in a previous lecture. The narrowband FM modulator generates a narrowband FM signal using simple components such as an integrator (an OpAmp), oscillators, multipliers, and adders. The generated narrowband FM signal can be converted to a wideband FM signal by simply passing it through a non–linear device with power P. Both the carrier frequency and the frequency deviation Δf of the narrowband signal

are increased by a factor P. Sometimes, the desired increase in the carrier frequency and the desiredincreasein $\Delta f$are different. Inthis case, we increase Δf to thedesiredvalue anduse a frequency shifter (multiplication by a sinusoid followed by a BPF) to change the carrier frequency to the desired value.

SINGLE-TONEFREQUENCYMODULATION

Time-DomainExpression

Since the FM wave is a nonlinear function of the modulating wave, the frequency modulation is a nonlinear process. The analysis of nonlinear process is the difficult task. In this section, we will study single-tone frequency modulation in detail to simplify the analysis and to get thorough understanding about FM.

Letusconsiderasingle-tonesinusoidalmessagesignaldefinedby

$$n(t) = A_n \cos(2nf_n t) \tag{5.13}$$

The instantaneous frequency from Eq. (5.8) is then

$$f(t) = f_c + k_f A_n \cos(2nf_n t) = f_c + \Delta f \cos(2nf_n t) \tag{5.14}$$

where

$$\Delta f = k_f A_n$$

$$\theta(t) = 2\pi f_c t + 2\pi k_f \int_0^t A_m \cos(2\pi f_m t) dt$$

$$= 2\pi f_c t + 2\pi k_f \frac{A_m}{2\pi f_m} \sin(2\pi f_m t)$$

$$= 2\pi f_c t + \frac{k_f A_m}{f_m} \sin(2\pi f_m t)$$

$$= 2\pi f_c t + \frac{\Delta f}{f_m} \sin(2\pi f_m t)$$

$$\therefore \theta(t) = 2\pi f_c t + \beta_f \sin(2\pi f_m t)$$

Where

$$\beta_f = \frac{\Delta f}{f_m} = \frac{k_f A_m}{f_m}$$

is the modulation index of the FM wave. Therefore, the single-tone FM wave is expressed by

$$s_{FM}(t) = A_c \cos[2\pi f_c t + \beta_f \sin(2\pi f_n t)] \qquad (5.18)$$

This is the desired time-domain expression of the single-tone FM wave

Similarly, **single-tone phase modulated wave** may be determined from Eq. as

$$s_{PM}(t) = A_c \cos[2\pi f_c t + k_p A_n \cos(2\pi f_n t)]$$

$$\text{or, } s_{PM}(t) = A_c \cos[2\pi f_c t + \beta_p \cos(2\pi f_n t)] \qquad (5.19)$$

where

$$\beta_p = k_p A_n \qquad (5.20)$$

isthemodulationindexofthesingle-tonephasemodulatedwave. The frequency deviation of the single-tone PM wave is

$$s_{FM}(t) = A_c \cos\left[2\pi f_c t + \beta_f \sin(2\pi f_m t)\right]$$

SpectralAnalysisofSingle-ToneFMWave

TheaboveEq.canbe rewrittenas

$$s_{FM}(t) = Re\{A_c e^{j2\pi f_c t} e^{j\beta \sin(2\pi f_n t)}\}$$

For simplicity, the modulation index of FM has been considered as β instead ofβ_fafterward.Sincesin$(2\pi f_n t)$isperiodicwithfundamentalperiodT$=1/f_n$,the complexexpontiale$^{j\beta \sin(2\pi f_n t)}$isalsoperiodicwiththesamefundamentalperiod. Therefore, this complex exponential can be expanded in Fourier series representation as

$$e^{j\beta \sin(2\pi f_m t)} = \sum_{n=-\infty}^{\infty} c_n e^{j2\pi n f_m t}$$

wheretheFourierseriescoefficientsc$_n$areobtainedas

$$c_n = \frac{1}{T} \int_{-T/2}^{T/2} e^{j\beta \sin(2\pi f_m t)} e^{-j2\pi n f_m t} dt \qquad (5.24)$$

Let $2\pi f_m t = x$, then Eq. (5.24) reduces to

$$c_n = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{j\beta \sin(x)} e^{-jnx} dx = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{j(\beta \sin(x) - nx)} dx \qquad (5.25)$$

The integral on the right-hand side is known as the nth order Bessel function of the first kind and is denoted by $J_n(\beta)$. Therefore, $c_n = J_n(\beta)$ and Eq. (4.23) can be written as

$$e^{j\beta \sin(2\pi f_m t)} = \sum_{n=-\infty}^{\infty} J_n(\beta) e^{j2\pi n f_m t} \qquad (5.26)$$

By substituting Eq. (5.26) in Eq. (5.22), we get

$$s_{FM}(t) = \text{Re}\left\{ A_c \sum_{n=-\infty}^{\infty} J_n(\beta) e^{j2\pi n f_m t} e^{j2\pi f_c t} \right\}$$

$$= A_c \sum_{n=-\infty}^{\infty} J_n(\beta) \cos[2\pi(f_c + n f_m)t] \qquad (5.27)$$

Taking Fourier transform of Eq. (5.27), we get

$$S(f) = \frac{1}{2} A_c \sum_{n=-\infty}^{\infty} J_n(\beta)[\delta(f - f_c - n f_m) + \delta(f + f_c + n f_m)] \qquad (5.28)$$

From the spectral analysis we see that there is a carrier component and a number of side-frequencies around the carrier frequency at $\pm n f_m$.

The Bessel function may be expanded in a power series given by

$$J_n(\beta) = \sum_{k=0}^{\infty} \frac{(-1)^k \left(\frac{1}{2}\beta\right)^{n+2k}}{k! \, (k+n)!} \qquad (5.29)$$

Plots of Bessel function $J_n(\beta)$ versus modulation index β for $n = 0, 1, 2, 3, 4$ are shown in Figure 5.3.
Figure 5.3 Plot of Bessel function as a function of modulation index.

Figure 5.3 shows that for any fixed value of n, the magnitude of $J_n(\beta)$ decreases as β increases. One property of Bessel function is that

$$J_{-n}(\beta) = \begin{cases} J_n(\beta), & n \text{ even} \\ -J_n(\beta), & n \text{ odd} \end{cases} \tag{5.30}$$

One more property of Bessel function is that

$$\sum_{n=-\infty}^{\infty} J_n^2(\beta) = 1 \tag{5.31}$$

(iii) The average power of the FM wave remains constant. To prove this, let us determine the average power of Eq. (5.27) which is equal to

$$P = \frac{1}{2} A_c^2 \sum_{n=-\infty}^{\infty} J_n^2(\beta)$$

Using Eq. (5.31), the average power P is now

$$P = \frac{1}{2} A_c^2$$

TRANSMISSIONBANDWIDTHOFFMWAVE

The transmission bandwidth of an FM wave depends on the modulation index þ. The modulation index, on the other hand, depends on the modulating amplitude and modulating frequency. It isalmost impossible to determine the exact bandwidthofthe FMwave. Rather, we use a rule-of-thumb expression for determining the FM bandwidth.

Forsingle-tonefrequencymodulation,theapproximatedbandwidthisdeterminedby the expression

$$B = 2(\Delta f + f_m) = 2(\beta + 1)f_m = 2\Delta f \left(1 + \frac{1}{\beta}\right)$$

Thisexpressionisregardedasthe Carson'srule.TheFMbandwidthdeterminedby this rule accommodates at least 98 % of the total power.

Foranarbitrarymessagesignaln(t)withbandwidthormaximumfrequencyW,the bandwidth of the corresponding FM wave may be determined by Carson's rule as

$$B = 2(\Delta f + W) = 2(D + 1)W = 2\Delta f \left(1 + \frac{1}{D}\right)$$

GENERATIONOFFMWAVES

FMwavesarenormallygeneratedbytwomethods:indirectmethodanddirectmethod.

IndirectMethod(ArmstrongMethod)ofFMGeneration

Inthismethod,narrow-bandFMwave isgeneratedfirst byusing phase modulatorand then the wideband FM with desired frequency deviation is obtained by using frequency multipliers.

$$s(t) = A_c \cos\left[2\pi f_c t + 2\pi k_f \int_o^t m(t)dt\right]$$

$$or, s(t) = A_c \cos[2\pi f_c t + \emptyset(t)]$$

$$\emptyset(t) = 2\pi k_f \int_o^t m(t)dt$$

$$s(t) = A_c \cos(2\pi f_c t) \cos[\emptyset(t)] - A_c \sin(2\pi f_c t) \sin[\emptyset(t)]$$

TheaboveeqistheexpressionfornarrowbandFM wave

Inthiscase
$$\cos[\emptyset(t)] \approx 1 \text{ and } \sin[\emptyset(t)] \approx \emptyset(t)$$

$$s(t) = A_c \cos(2\pi f_c t) - A_c \sin(2\pi f_c t)\emptyset(t)$$

$$\text{or, } s(t) = A_c \cos(2\pi f_c t) - 2\pi A_c k_f \sin(2\pi f_c t) \int_0^t m(t) dt$$

Fig:NarrowbandFMGenerator

The frequency deviation Δf is very small in narrow-band FM wave. To produce wideband FM, we have to increase the value of Δf to a desired level. This is achieved by meansofoneor multiple frequencymultipliers. Afrequencymultiplier consistsofa nonlinear device and a bandpass filter. The nth order nonlinear device produces a dc component and n number offrequencymodulatedwaveswithcarrier frequencies $f_c, 2f_c, ... nf_c$andfrequency deviations Δf, $2\Delta f$, … $n\Delta f$,respectively.Ifwe want an FM wave with frequency deviation of $6\Delta f$, then we may use a 6th order nonlinear device or one 2nd order and one 3rd order nonlinear devices incascade followed bya bandpass filter centered at $6f_c$.Normally, we may require very high value of frequency deviation. This automatically increases the carrier frequency by the same factor which may be higher than the required carrier frequency. We may shift the carrier frequency to the desired level byusing mixer which does not change the frequencydeviation.

The narrowband FM has some distortion due to the approximation made in deriving theexpressionofnarrowband FM fromthegeneral expression. Thisproducessomeamplitude modulation in the narrowband FM which is removed by using a limiter in frequency multiplier.

Direct Method of FM Generation

In this method, the instantaneous frequency $f(t)$ of the carrier signal c(t) is varied directly with the instantaneous value of the modulating signal n(t). For this, an oscillator is used in which anyone of the reactive components (either C or L) of the resonant network of the oscillator is varied linearly with n(t). We can use a varactor diode or a varicap as a voltage-variable capacitor whose capacitance solely depends on the reverse-bias voltage applied across it. To vary such capacitance linearly with n(t), we have to reverse-bias the diode by the fixed DC voltage and operate within a small linear portion of the capacitance-voltage characteristic curve. The unmodulated fixed capacitance C_0 is linearly varied by n(t) such that the resultant capacitance becomes

$C(t)=C_0-kn(t)$

where the constant k is the sensitivity of the varactor diode (measured in capacitance per volt).
fig:Hartley oscillator for FM generation

The above figure shows the simplified diagram of the Hartley oscillator in which is implemented the above discussed scheme. The frequency of oscillation for such an oscillator is given

$$f(t) = \frac{1}{2\pi\sqrt{(L_1 + L_2)C(t)}}$$

$$f(t) = \frac{1}{2\pi\sqrt{(L_1 + L_2)(C_0 - km(t))}}$$

$$= \frac{1}{2\pi\sqrt{(L_1 + L_2)C_0}} \frac{1}{\sqrt{1 - \frac{km(t)}{C_0}}}$$

or, $\quad f(t) = f_c \left(1 - \frac{km(t)}{C_0}\right)^{-1/2}$

where f_c is the unmodulated frequency of oscillation. Assuming,

$$\frac{km(t)}{C_0} \ll 1$$

we have from binomial expansion,

$$\left(1 - \frac{km(t)}{C_0}\right)^{-1/2} \approx 1 + \frac{km(t)}{2C_0}$$

$$f(t) \approx f_c\left(1 + \frac{km(t)}{2C_0}\right)$$

$$= f_c + \frac{kf_cm(t)}{2C_0}$$

$$\text{or, } f(t) = f_c + k_f m(t)$$

$$k_f = \frac{kf_c}{2C_0}$$

isthe frequencysensitivityofthe modulator.TheEq. (5.42) istherequiredexpressionfor the instantaneous frequency of an FM wave. In this way, we can generate an FM wave by direct method.

Direct FM may be generated also bya device in which the inductance ofthe resonant circuit is linearly varied by a modulating signal n(t); in this case the modulating signal being the current.

The main advantage of the direct method is that it produces sufficiently highfrequency deviation, thus requiring little frequency multiplication. But, it has poor frequency stability. A feedback scheme is used to stabilize the frequency in which the output frequency is compared with the constant frequency generated by highly stable crystal oscillator and the error signal is feedback to stabilize the frequency.

DEMODULATIONOFFMWAVES

The processto extractthe message signalfroma frequency modulated wave is known as frequency demodulation. As the information in an FM wave is contained in its instantaneous frequency, the frequency demodulator has the task of changing frequency variations to amplitude variations. Frequency demodulation method is generally categorized into two types: direct method and indirect method. Under direct method category, we will discuss about limiter discriminator method and under indirect method, phase-locked loop (PLL) will be discussed.

LimiterDiscriminatorMethod

Recalling theexpressionofFMsignal,

$$s(t)=A_c\cos[2\pi f_c t+2\pi k_f \int_0^t n(t)dt]$$

Inthis method, extractionofn(t)fromtheaboveequationinvolvesthethreesteps: amplitude limit, discrimination, and envelope detection.

    A. Amplitude Limit

During propagation of the FM signal from transmitter to receiver theamplitude of the FM wave (supposed to be constant) may undergo changes due to fading and noise. Therefore, before further processing, the amplitude of the FMsignalis limited to reducethe effect of fading and noise byusing limiter as discussed in the section 5.9. The amplitude limitation will not affect the message signal as the amplitude of FM does not carry any information of the message signal.

    B. Discrimination/Differentiation

Inthisstep wedifferentiatethe FMsignalasgivenby

$$\frac{ds(t)}{dt}=\frac{d}{dt}\left\{A_c\cos\left[2\pi f_c t+2\pi k_f\int_0^t m(t)dt\right]\right\}$$

$$=\frac{d\left\{A_c\cos\left[2\pi f_c t+2\pi k_f\int_0^t m(t)dt\right]\right\}}{d\left\{2\pi f_c t+2\pi k_f\int_0^t m(t)dt\right\}}\frac{d\left\{2\pi f_c t+2\pi k_f\int_0^t m(t)dt\right\}}{dt}$$

$$=-A_c\left[2\pi f_c+2\pi k_f m(t)\right]\sin\left[2\pi f_c t+2\pi k_f\int_0^t m(t)dt\right]$$

Hereboththeamplitude andfrequencyofthis signalaremodulated.

In this case, the differentiator is nothing but a circuit that converts change in frequency into corresponding change in voltage or current as shown in Fig. 5.11. The ideal differentiator has transfer function

$$H(jw)=j2\pi f$$
Figure: Transfer function of ideal differentiator.

Instead of ideal differentiator, any circuit can be used whose frequency response is linear for some band in positive slope. This method is known as slope detection. For this, linear segment with positive slope of RC high pass filter or LC tank circuit can be used. Figure 5.13 shows the use of an LC circuit as a differentiator. The drawback is the limited linear portion in the

slope of the tank circuit. This is not suitable for wideband FM where the peak frequency deviation is high.
Figure: Use of LC tank circuit as a differentiator.

A better solution is the ratio or balanced slope detector in which two tank circuits tuned at $f_c + \Delta f$ and $f_c - \Delta f$ are used to extend the linear portion as shown in below figure.
Figure: Frequencyresponseofbalancedslopedetector.

AnotherdetectorcalledFoster-seelydiscriminatoreliminatestwotankcircuitsbut still offer the same linear as the ratio detector.

C. EnvelopeDetection

Thethirdstepistosendthedifferentiatedsignaltotheenvelopedetectorto recoverthe message signal.

Phase-LockedLoop(PLL)asFMDemodulator

A PLL consists ofa multiplier, a loop filter, and a VCO connected together to forma feedback loop as shown in Fig. 5.15. Let the input signal be an FM wave as definedby

$$s(t)=A_c\cos[2\pi f_c t+\emptyset_1(t)]$$

$$\emptyset_1(t) = 2\pi k_f \int_0^t m(t)dt$$

Fig:PLL Demodulator

Let the VCO output be defined by

$$v_{VCO}(t) = A_v \sin[2\pi f_c t + \emptyset_2(t)]$$

where

$$\emptyset_2(t) = 2\pi k_v \int_0^t v(t)dt$$

Here k_v is the frequency sensitivity of the VCO measured in hertz per volt. The multiplication of $s(t)$ and $v_{VCO}(t)$ results

$$s(t)v_{VCO}(t) = A_c \cos[2\pi f_c t + \emptyset_1(t)] A_v \sin[2\pi f_c t + \emptyset_2(t)]$$

$$= \frac{A_c A_v}{2} \sin[4\pi f_c t + \emptyset_1(t) + \emptyset_2(t)] + \frac{A_c A_v}{2} \sin[\emptyset_2(t) - \emptyset_1(t)]$$

The high-frequency component is removed by the low-pass filtering of the loop filter. Therefore, the input signal to the loop filter can be considered as

$$e(t) = \frac{A_c A_v}{2} \sin[\emptyset_2(t) - \emptyset_1(t)]$$

The difference $\emptyset_2(t) - \emptyset_1(t) = \emptyset_e(t)$ constitutes the phase error. Let us assume that the PLL is in phase lock so that the phase error is very small. Then,

$$\sin[\emptyset_2(t) - \emptyset_1(t)] \approx \emptyset_2(t) - \emptyset_1(t)$$

$$\emptyset_e(t) = 2\pi k_v \int_0^t v(t)dt - \emptyset_1(t)$$

$$e(t) = \frac{A_c A_v}{2} \emptyset_e(t)$$

Differentiating Eq. (5.48) with respect to time, we get

$$\frac{d\emptyset_e(t)}{dt} = 2\pi k_v v(t) - \frac{d\emptyset_1(t)}{dt}$$

Since

$$v(t) = e(t) * h(t) = \frac{A_c A_v}{2}[\emptyset_e(t) * h(t)]$$

Eq. (5.50) becomes

$$\frac{d\emptyset_e(t)}{dt} = 2\pi k_v \frac{A_c A_v}{2}[\emptyset_e(t) * h(t)] - \frac{d\emptyset_1(t)}{dt}$$

$$or, \pi k_v A_c A_v[\emptyset_e(t) * h(t)] - \frac{d\emptyset_e(t)}{dt} = \frac{d\emptyset_1(t)}{dt}$$

Taking Fourier transform of Eq. (5.52), we get

$$\pi k_v A_c A_v \emptyset_e(f)H(f) - j2\pi f\emptyset_e(f) = j2\pi f\emptyset_1(f)$$

$$or, \emptyset_e(f) = \frac{j2\pi f}{\pi k_v A_c A_v H(f) - j2\pi f}\emptyset_1(f)$$

$$or, \emptyset_e(f) = \frac{1}{\frac{\pi k_v A_c A_v}{j2\pi f}H(f) - 1}\emptyset_1(f)$$

Fourier transform of Eq. (5.51) is

$$V(f) = \frac{A_c A_v}{2}\emptyset_e(f)H(f)$$

Substituting Eq. (5.53) into (5.54), we get

$$V(f) = \frac{A_c A_v}{2}\frac{1}{\frac{\pi k_v A_c A_v}{j2\pi f}H(f) - 1}\emptyset_1(f)H(f)$$

We design $H(f)$ such that

$$\left|\frac{\pi k_v A_c A_v}{j2\pi f}H(f)\right| \gg 1$$

in the frequency band $|f| < W$ of the message signal.

/8

$$\therefore V(f) = \frac{A_c A_v}{2}\frac{1}{\frac{\pi k_v A_c A_v}{j2\pi f}H(f)}\emptyset_1(f)H(f)$$

$$or, V(f) = \frac{1}{2\pi k_v}j2\pi f\emptyset_1(f)$$

Taking inverse Fourier transform of Eq. (4.56), we get

$$v(t) = \frac{1}{2\pi k_v}\frac{d\emptyset_1(t)}{dt}$$

$$= \frac{1}{2\pi k_v}\frac{d}{dt}\left\{2\pi k_f \int_0^t m(t)dt\right\}$$

$$= \frac{1}{2\pi k_v}2\pi k_f m(t)$$

$$\therefore v(t) = \frac{k_f}{k_v}m(t)$$

Since the control voltage of the VCO is proportional to the message signal, $v(t)$ is the demodulated signal.

We observe that the output of the loop filter with frequency response $H(f)$ is the desired messagesignal. HencethebandwidthofH(f) should bethesameasthebandwidthW ofthe messagesignal. Consequently, thenoiseattheoutputofthe loopfilter isalso limitedto the bandwidthW. Onthe other hand, theoutput fromthe VCO is a wideband FM signalwith an instantaneous frequency that follows the instantaneous frequency of the received FM signal.

PREEMPHASISANDDEEMPHASISNETWORKS

In FM, the noise increases linearly with frequency. By this, the higher frequency components of message signal are badly affected by the noise. To solve this problem, we can use a preemphasis filter oftransfer function $H_p(f)$ at the transmitterto boost the higher frequency components before modulation. Similarly, at the receiver, the deemphasis filter of transfer function $H_d(f)$ can be used after demodulator to attenuate the higher frequency components thereby restoring the original message signal.

Thepreemphasis networkandits frequencyresponseareshowninFigure5.19 (a) and(b) respectively. Similarly, thecounterpart for deemphasis networkisshown in Figure 5.20.
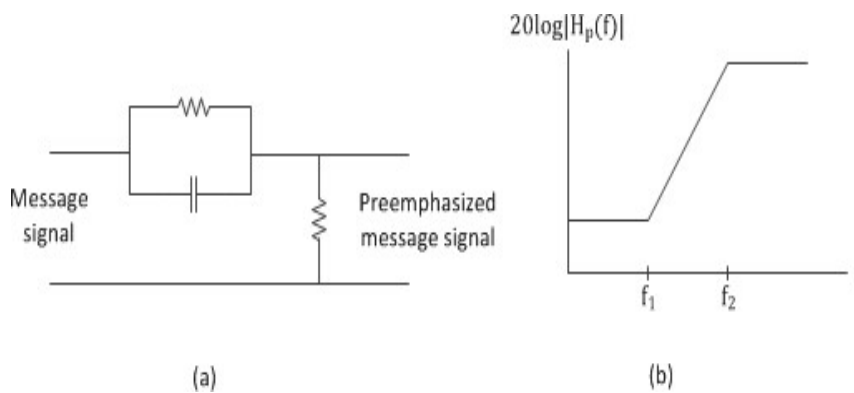

Figure;(a)Preemphasisnetwork.(b)Frequencyresponseofpreemphasisnetwork.
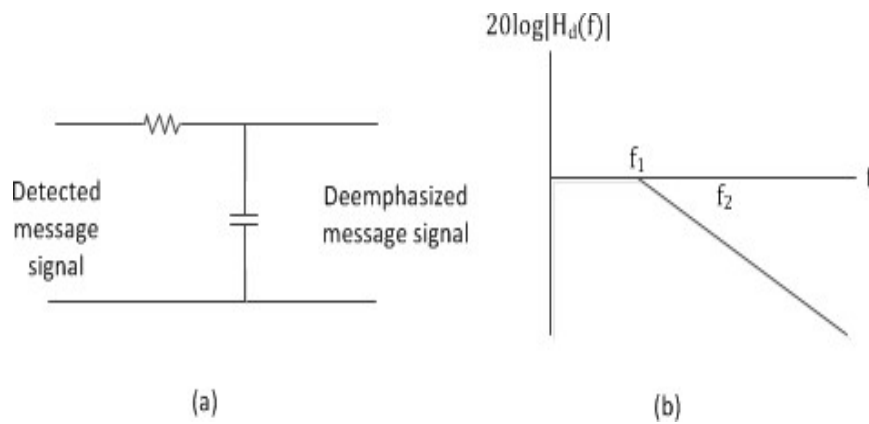

Figure(a)Deemphasisnetwork.(b)FrequencyresponseofDeemphasis network.

InFMbroadcasting,f_1 and$f_2$arenormallychosentobe2.1 kHzand30kHz respectively.

The frequencyresponseofpreemphasisnetworkis

$$H_p(f) = \left(\frac{w_2}{w_1}\right)\frac{jw + w_1}{jw + w_2}$$

Here, $w = 2\pi f$ and $w_1 = 2\pi f_1$. For $w \ll w_1$,

$$H_p(f) \approx 1$$

And for $w_1 \ll w \ll w_2$,

$$H_p(f) \approx \frac{j2\pi f}{w_1}$$

So, the amplitude of frequency components less than 2.1 kHz are left unchanged and greater than that are increased proportional to f.

The frequency response of deemphasis network is

$$H_d(f) = \frac{w_1}{j2\pi f + w_1}$$

For $w \ll w_2$,

$$H_p(f) \approx \frac{j2\pi f + w_1}{w_1}$$

such that

$$H_p(f)H_d(f) \approx 1$$

over the baseband of 0 to 15 KHz.

FM Transmitter

TheFMtransmitter isasingletransistorcircuit.Inthetelecommunication, thefrequency modulation (FM)transfers the information by varying the frequency of carrier wave according to the message signal. Generally, the FM transmitter uses VHF radio frequencies of 87.5 to 108.0 MHz to transmit & receive the FM signal. This transmitter accomplishes the most excellent range with less power. The performance and working ofthe wireless audio transmitter circuit is depends on the induction coil & variable capacitor. This article will explain about the working of the FM transmitter circuit with its applications.

The FM transmitter is a low power transmitter and it uses FM waves for transmitting the sound, this transmitter transmits the audio signals through the carrier wave by the difference of frequency. The carrier wave frequency is equivalent to the audio signal of the amplitude and the FM transmitter produce VHF band of 88 to 108MHZ.Plese follow the below link for: Know all About Power Amplifiers for FM Transmitter
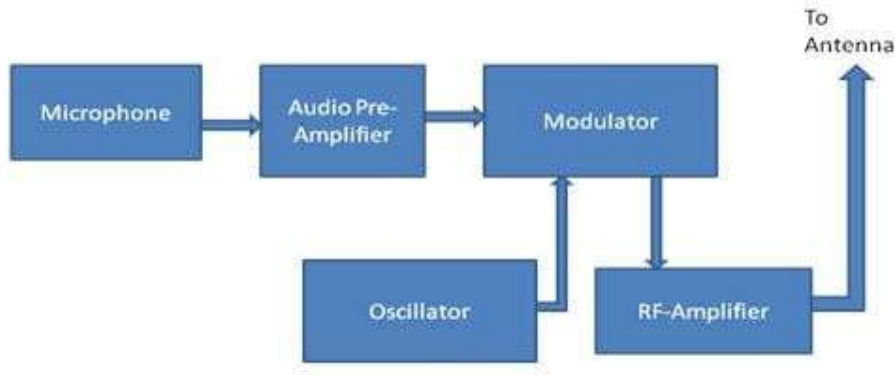

BlockDiagramofFMTransmitter

WorkingofFMTransmitterCircuit

The following circuit diagram shows the FM transmitter circuit and the required electricaland electronic components for this circuit is the power supplyof 9V, resistor, capacitor, trimmer capacitor, inductor, mic, transmitter, and antenna. Let us consider the microphone to understand the sound signals and inside the mic there is a presence of capacitive sensor. It produces according to the vibration to the change of air pressure and the AC signal.
FMTransmittercircuit

The formation ofthe oscillating tank circuit can be done throughthe transistor of 2N3904 by using the inductor and variable capacitor. The transistor used in this circuit is an NPN transistor used for general purpose amplification. If the current is passed at the inductor L1 and variable capacitor then the tank circuit will oscillate at the resonant carrier frequency of the FM modulation. The negative feedback will be the capacitor C2 to the oscillating tank circuit.

To generate the radio frequency carrier waves the FM transmitter circuit requires an oscillator.ThetankcircuitisderivedfromtheLCcircuittostoretheenergyforoscillations.

The input audio signal fromthe mic penetrated tothe base ofthe transistor, which modulates the LC tank circuit carrier frequency in FM format. The variable capacitor is used to change theresonant frequencyfor fine modificationtotheFMfrequencyband.The modulatedsignal from the antenna is radiated as radio waves at the FM frequency band and the antenna is nothing but copper wire of 20cm long and 24 gauge. In this circuit the length ofthe antenna should be significant and here you can use the 25-27 inches long copper wire ofthe antenna.

Noiseincommunicationsystem

A signal may be contaminated along the path by noise. Noise may be defined as any unwanted introduction of energy into the desired signal. In radio receivers, noise may produce "hiss" in the loudspeaker output. Noise is random and unpredictable.

Noise is produced both external and internal to the system. External noise includes atmospheric noise (e.g., from lightning), galactic noise (thermal radiation from cosmic bodies), and industrial noise (e.g., from motors, ignition). We can minimize or eliminate external noise by proper system design. On the other hand, internal noise is generated inside the system. It is resulted due to random motion of charged particles in resistors, conductors, and electronic devices. With proper system design, it can be minimized but never can be eliminated. This is the major constraint in the rate of telecommunications.

Noise temperature

Equivalent noisetemperatureisnotthephysicaltemperatureofamplifier,but atheoretical construct, that is an equivalent temperature that produces that amount of noise power

$T_e=(F-1)$

Whitenoise

One of the very important random processes is the *white noise* process. Noises in manypracticalsituationsareapproximatedbythewhite noiseprocess.Most importantly,the white noise plays an important role in modelling of WSS signals.

A white noise process $\{W(t)\}$ is a randomprocess that has constant power spectraldensityat all frequencies. Thus

$$S_W(\omega) = \frac{N_0}{2} \qquad\qquad -\infty < \omega < \infty$$

where N_0 is a real constant and called the *intensity* of the white noise. The corresponding autocorrelation function is given by

$$R_W(\tau) = \frac{N}{2}\delta(\tau)$$ where $\delta(\tau)$ is the Dirac delta.

The average power of white noise

$$P_{avg} = EW^2(t) = \frac{1}{2\pi}\int_{-\infty}^{\infty} \frac{N}{2}d\omega \to \infty$$

The autocorrelation function and the PSD of a white noise process is shown in Figure 1 below.
fig: autocorrelation and psd of white noise

NARROWBAND NOISE (NBN)

In most communication systems, we are often dealing with band-pass filtering of signals. Wideband noise will be shaped into bandlimited noise. If the bandwidth of the band limited noise is relatively small compared to the carrier frequency, we refer to this as *narrowband noise*.

the narrowband noise is expressed as as

$$n(t) = x(t)\cos 2\pi f_C t - y(t)\sin 2\pi f_C t$$

where f_C is the carrier frequency within the band occupied by the noise. $x(t)$ and $y(t)$ are known as the *quadrature components* of the noise $n(t)$. The Hibert transform of

$n(t)$ is

Proof.

The Fourier transform of $n(t)$ is

$$N(f) = \frac{1}{2}X(f-f_c) + \frac{1}{2}X(f+f_c) + \frac{1}{2}jY(f-f_c) - \frac{1}{2}jY(f+f_c)$$

Let $\hat{N}(f)$ be the Fourier transform of $n^{\wedge}(t)$. In the frequency domain, $\hat{N}(f) = N(f)[-j\,\text{sgn}(f)]$. We simply multiply all positive frequency components of $N(f)$ by $-j$ and all negative frequency components of $N(f)$ by j. Thus

$$\hat{n}(t) = H[n(t)] = x(t)\sin 2\pi f_c t + y(t)\cos 2\pi f_c t$$

$$\hat{N}(f) = -j\frac{1}{2}X(f-f_c) + j\frac{1}{2}X(f+f_c) - j\frac{1}{2}jY(f-f_c) - j\frac{1}{2}jY(f+f_c)$$

$$\hat{N}(f) = -j\frac{1}{2}X(f-f_c) + j\frac{1}{2}X(f+f_c) + \frac{1}{2}Y(f-f_c) + \frac{1}{2}Y(f+f_c)$$
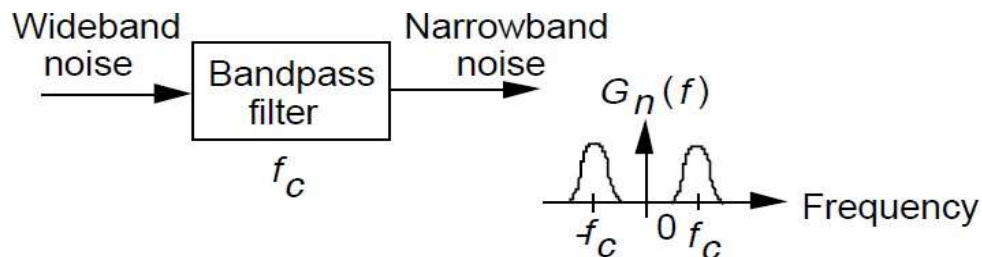

and the inverse Fourier transform of $\hat{N}(f)$ is

$$\hat{n}(t) = x(t)\sin 2\pi f_c t + y(t)\cos 2\pi f_c t$$

The quadrature components $x(t)$ and $y(t)$ can now be derived from equations

$$x(t) = n(t)\cos 2\pi f_c t + n^{\wedge}(t)\sin 2\pi f_c t$$

and

$$y(t) = n(t)\cos 2\pi f_c t - n^{\wedge}(t)\sin 2\pi f_c t$$

Fig: generation of narrowband noise
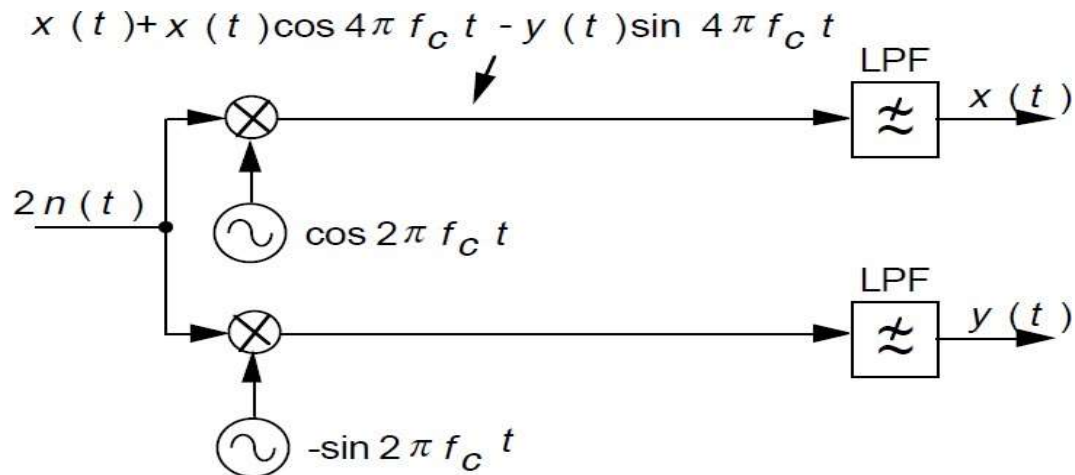

$$x(t) + x(t)\cos 4\pi f_c t - y(t)\sin 4\pi f_c t$$

Fig: Generation of quadrature components of $n(t)$.

o Filters at the receiver have enough bandwidth to pass the desired signal but not too big to pass excess noise.

o Narrowband(NB) fc center frequency is much bigger that the bandwidth.

o Noise at the output of such filters is called narrowband noise(NBN).

o NBN has spectral concentrated about some mid-band frequency f_c

o The sample function of such NBN $n(t)$ appears as a sine wave of frequency f_c which modulates slowly in amplitude and phase

Input signal-to-noise ratio (SNR_I): is the ratio of the average power of modulated signal $s(t)$ to the average power of the filtered noise.

Output signal-to-noise ratio (SNR_O): is the ratio of the average power of demodulated message to the average power of the noise, both measured at the receiver output.

Channel signal-to-noise ratio (SNR_C): is the ratio of the average power of modulated signal $s(t)$ to the average power of the noise in the message bandwidth, both measured at the receiver input.

Noisefigure

The Noise figure is the amount of noise power added by the electronic circuitry in thereceiver to the thermal noise power from the input of the receiver. The thermal noise at the input to the receiver passes through to the demodulator. This noise is present in the receive channeland cannot be removed. The noise figure ofcircuits inthe receiver suchasamplifiers and mixers, adds additional noise to the receive channel. This raises the noise floor at the demodulator.

$$Noise\ Figure = \frac{Signal\ to\ noise\ ratio\ at\ input}{Signal\ to\ noise\ ratio\ at\ output}$$

NoiseBandwidth

A filter's equivalent noise bandwidth (ENBW) is defined as the bandwidth of a perfect rectangular filter that passes the same amount of power as the cumulative bandwidth of the channelselective filters inthe receiver. At thispoint we would like to knowthe noise floor in our receiver, i.e. the noise power in the receiver intermediate frequency(IF) filter bandwidth that comes from kTB. Since the units of kTB are Watts/ Hz, calculate the noise floor in the channel bandwidth by multiplying the noise power in a 1 Hz bandwidth by the overall equivalent noise bandwidth in Hz.

NOISEINDSB-SCSYSTEM:

Letthetransmittedsignalis

$$u(t) = A_c m(t) \cos(2\pi f_c t)$$

The received signalat the output ofthe receiver noise- limiting filter : Sumof this signaland filterednoise.Afilterednoiseprocesscanbeexpressed intermsofitsin-phaseandquadrature components as

$$n(t) = A(t)\cos[2\pi f_c t + \theta(t)] = A(t)\cos\theta(t)\cos(2\pi f_c t) - A(t)\sin\theta(t)\sin(2\pi f_c t)$$
$$= n_c(t)\cos(2\pi f_c t) - n_s(t)\sin(2\pi f_c t)$$

where$n_c(t)$isin-phasecomponentand$n_s(t)$isquadraturecomponent

Received signal (Adding the filtered noise to the modulated signal)

$$r(t) = u(t) + n(t)$$
$$= A_c m(t) \cos(2\pi f_c t) + n_c(t) \cos(2\pi f_c t) - n_s(t) \sin(2\pi f_c t)$$

Demodulate the received signal by first multiplying r(t) by a locally generated sinusoid $\cos(2f_c t + \phi)$, where ϕ is the phase of the sinusoid. Then passing the product signal through an ideal lowpass filter having a bandwidth W.

The multiplication of r(t) with cos(2πfct + φ) yields

$$r(t)\cos(2\pi f_c t + \phi)$$
$$= u(t)\cos(2\pi f_c t + \phi) + n(t)\cos(2\pi f_c t + \phi)$$
$$= A_c m(t)\cos(2\pi f_c t)\cos(2\pi f_c t + \phi)$$
$$+ n_c(t)\cos(2\pi f_c t)\cos(2\pi f_c t + \phi) - n_s(t)\sin(2\pi f_c t)\cos(2\pi f_c t + \phi)$$
$$= \tfrac{1}{2} A_c m(t)\cos(\phi) + \tfrac{1}{2} A_c m(t)\cos(4\pi f_c t + \phi)$$
$$+ \tfrac{1}{2}\left[n_c(t)\cos(\phi) + n_s(t)\sin(\phi) \right] + \tfrac{1}{2}\left[n_c(t)\cos(4\pi f_c t + \phi) - n_s(t)\sin(4\pi f_c t + \phi) \right]$$

The lowpass filter rejects the double frequency components and passes only the lowpass components.

$$y(t) = \tfrac{1}{2} A_c m(t)\cos(\phi) + \tfrac{1}{2}\left[n_c(t)\cos(\phi) + n_s(t)\sin(\phi) \right]$$

the effect of a phase difference between the received carrier and a locally generated carrier at the receiver is a drop equal to $cos(^2 \phi)$ in the received signal power.

Phase-locked loop

The effect of a phase-locked loop is to generate phase of the received carrier at the receiver.
If a phase-locked loop is employed, then $\phi=0$ and the demodulator is called a
coherent or synchronous demodulator.

In our analysis in this section, we assume that we are employing a coherent demodulator. With this assumption, we assume that $\phi=0$

$$y(t) = \tfrac{1}{2}\left[A_c m(t) + n_c(t) \right]$$

Therefore, at the receiver output, the message signal and the noise components are additive and we are able to define a meaningful SNR. The message signal power is given by

$$P_o = \frac{A_c^2}{4} P_M$$

Power P_M is the content of the message signal The

noise power is given by

$$P_{n_o} = \frac{1}{4} P_{n_c} = \frac{1}{4} P_n$$

The power content of n(t) can be found by noting that it is the result of passing n_w(t) through a filter with bandwidth B_c. Therefore, the power spectral density of n(t) is given by

$$S_n(f) = \begin{cases} \frac{N_0}{2} & |f - f_c| < W \\ 0 & otherwise \end{cases}$$

The noise power is

$$P_n = \int_{-\infty}^{\infty} S_n(f) df = \frac{N_0}{2} \times 4W = 2WN_0$$

Now we can find the output SNR as

$$\left(\frac{S}{N}\right)_o = \frac{P_o}{P_{n_o}} = \frac{\frac{A_c^2}{4} P_M}{\frac{1}{4} 2WN_0} = \frac{A_c^2 P_M}{2WN_0}$$

In this case, the received signal power, given by

$$P_R = A_c^2 P_M / 2.$$

The output SNR for DSB-SC AM may be expressed as

$$\left(\frac{S}{N}\right)_{o_{DSB}} = \frac{P_R}{N_0 W}$$

which is identical to baseband SNR.

In DSB-SC AM, the output SNR is the same as the SNR for a baseband system. DSB-SC AM does not provide any SNR improvement over a simple baseband communication system.

NOISE IN SSB-SC SYSTEM:

Let SSB modulated signal is

$$u(t) = A_c m(t) \cos(2\pi f_c t) \mp A_c \hat{m}(t) \sin(2\pi f_c t)$$

Input to the demodulator

$$r(t) = A_c m(t) \cos(2\pi f_c t) \mp A_c \hat{m}(t) \sin(2\pi f_c t) + n(t)$$
$$= A_c m(t) \cos(2\pi f_c t) \mp A_c \hat{m}(t) \sin(2\pi f_c t) + n_c(t) \cos(2\pi f_c t) - n_s(t) \sin(2\pi f_c t)$$
$$= [A_c m(t) + n_c(t)] \cos(2\pi f_c t) + [\mp A_c \hat{m}(t) - n_s(t)] \sin(2\pi f_c t)$$

Assumption: Demodulation with an ideal phase reference.

Hence, the output of the low pass filter is the in-phase component (with a coefficient of ½) of the preceding signal.

Parallel to our discussion of DSB, we have

$$P_o = \frac{A_c^2}{4} P_M$$

$$P_{n_0} = \frac{1}{4} P_{n_c} = \frac{1}{4} P_n$$

$$P_n = \int_{-\infty}^{\infty} S_n(f) df = \frac{N_0}{2} \times 2W = W N_0$$

$$\left(\frac{S}{N}\right)_0 = \frac{P_0}{P_{n_0}} = \frac{A_c^2 P_M}{W N_0}$$

$$P_R = P_U = A_c^2 P_M$$

$$\left(\frac{S}{N}\right)_{0_{SSB}} = \frac{P_R}{N_0 W} = \left(\frac{S}{N}\right)_b$$

The signal-to-noise ratio in an SSB system is equivalent to that of a DSB system.

Noise in Conventional AM

DSB AM signal : $\quad u(t) = A_c[1 + am_n(t)] \cos(2\pi f_c t)$

Received signal at the input to the demodulator

$$r(t) = A_c[1 + am_n(t)] \cos(2\pi f_c t) + n(t)$$
$$= A_c[1 + am_n(t)] \cos(2\pi f_c t) + n_c(t) \cos(2\pi f_c t) - n_s(t) \sin(2\pi f_c t)$$
$$= [A_c[1 + am_n(t)] + n_c(t)] \cos(2\pi f_c t) - n_s(t) \sin(2\pi f_c t)$$

Where $\quad$ a is the modulation index

$\quad\quad$ $m_n(t)$ is normalized so that its minimum value is -1

If a synchronous demodulator is employed, the situation is basically similar to the DSB case, except that we have $1 + am_n(t)$ instead of $m(t)$.

$$y(t) = \tfrac{1}{2}\left[A_c a m_n(t) + n_c(t)\right]$$

Received signal power

$$P_R = \frac{A_c^2}{2}\left[1 + a^2 P_{M_n}\right]$$

□ Assumed that the message process is zero mean.

Now we can derive the output SNR as

$$\left(\frac{S}{N}\right)_{0_{AM}} = \frac{\tfrac{1}{4}A_c^2 a^2 P_{M_n}}{\tfrac{1}{4}P_{n_c}} = \frac{A_c^2 a^2 P_{M_n}}{2N_0 W} = \frac{a^2 P_{M_n}}{1 + a^2 P_{M_n}}\frac{\frac{A_c^2}{2}\left[1 + a^2 P_{M_n}\right]}{N_0 W}$$

$$= \frac{a^2 P_{M_n}}{1 + a^2 P_{M_n}}\frac{P_R}{N_0 W} = \frac{a^2 P_{M_n}}{1 + a^2 P_{M_n}}\left(\frac{S}{N}\right)_b = \eta\left(\frac{S}{N}\right)_b$$

□ η denotes the modulation efficiency
□ Since $a^2 P_{M_n} < 1 + a^2 P_{M_n}$, the SNR in conventional AM is always smaller than the SNR in a baseband system.

➢ Inpracticalapplications,themodulation indexaisintherangeof0.8-0.9.

➢ Powercontentofthenormalizedmessageprocessdependsonthemessage source.

➢ Speechsignals:Largedynamicrange,$P_M$isabout0.1.

➢ The overall loss in SNR, when compared to a baseband system, is a factor of 0.075 or equivalent to a loss of 11dB.

The reason for this loss is that a large part ofthe transmitter power is used to send the carrier component of the modulated signal and not the desired signal. To analyze the envelope-detector performance in the presence of noise, we must use certain approximations.

Thisisaresultofthenonlinearstructureofanenvelopedetector,whichmakesanexact analysis difficult

Inthiscase,thedemodulatordetectstheenvelopeofthereceivedsignalandthenoise process.
Theinputtotheenvelopedetectoris

$$r(t) = \left[A_c[1 + a m_n(t)] + n_c(t)\right]\cos(2\pi f_c t) - n_s(t)\sin(2\pi f_c t)$$

Therefore,theenvelopeofr(t)isgivenby

$$V_r(t) = \sqrt{\left[A_c[1 + a m_n(t)] + n_c(t)\right]^2 + n_s^2(t)}$$

Now we assume that the signal component in $r(t)$ is much stronger than the noise component. Then

$$P\big(n_c(t) << A_c[1+am_n(t)]\big) \approx 1$$

Therefore, we have a high probability that

$$V_r(t) \approx A_c[1+am_n(t)]+n_c(t)$$

After removing the DC component, we obtain

$$y(t) = A_c am_n(t)+n_c(t)$$

which is basically the same as $y(t)$ for the synchronous demodulation without the ½ coefficient.

This coefficient, of course, has no effect on the final SNR. So we conclude that, under the assumption of high SNR at the receiver input, the performance of synchronous and envelope demodulators is the same.

However, if the preceding assumption is not true, that is, if we assume that, at the receiver input, the noise power is much stronger than the signal power, Then

$$V_r(t) = \sqrt{\big[A_c[1+am_n(t)]+n_c(t)\big]^2 + n_s^2(t)}$$

$$= \sqrt{A_c^2[1+am_n(t)]^2 + n_c^2(t)+n_s^2(t)+2A_c n_c(t)[1+am_n(t)]}$$

$$\xrightarrow{a} \sqrt{\big(n_c^2(t)+n_s^2(t)\big)\left[1+\frac{2A_c n_c(t)}{n_c^2(t)+n_s^2(t)}\big(1+am_n(t)\big)\right]}$$

$$\xrightarrow{b} V_n(t)\left[1+\frac{A_c n_c(t)}{V_n^2(t)}\big(1+am_n(t)\big)\right]$$

$$= V_n(t)+\frac{A_c n_c(t)}{V_n(t)}\big(1+am_n(t)\big)$$

(a): $A_c^2[1+am_n(t)]^2$ is small compared with the other components

(b): $\sqrt{n_c^2(t)+n_s^2(t)} = V_n(t)$;the envelope of the noise process

Use the approximation

$\sqrt{1+\varepsilon} \approx 1+\frac{\varepsilon}{2}$, for small ε. where $\varepsilon = \frac{2A_c n_c(t)}{n_c^2(t)+n_s^2(t)}\big(1+am_n(t)\big)$

Then
$$V_r(t) = V_n(t) + \frac{A_c n_c(t)}{V_n(t)}\left(1 + am_n(t)\right)$$

We observe that, at the demodulator output, the signal and the noise components are no longer additive. In fact, the signal component is multiplied by noise and is no longer distinguishable. In this case, no meaningful SNR can be defined. We say that this system is operating below the threshold. The subject of threshold and its effect on the performance of a communication system will be covered in more detail when we discuss the noise performance in angle modulation.

Effectofthresholdinanglemodulationsystem:

FM THRESHOLD EFFECT FM threshold is usually defined as a Carrier-to-Noise ratio at which demodulated Signal-to-Noise ratio falls 1dB below the linear relationship . This is the effect produced in an FM receiver when noise limits the desired information signal. It occurs at about 10 dB, as earlier stated in 5 the introduction, which is at a point where the FMsignal-to-Noise improvement is measured. Below the FM threshold point, the noise signal (whose amplitude and phase are randomly varying) may instantaneously have amplitude greater than that of the wanted signal. When this happens, the noise will produce a sudden change in the phase of the FM demodulator output. In an audio system, this sudden phase change makes a "click". In video applications the term"click noise" is used to describe short horizontal black and white lines that appear randomly over a picture

An important aspect ofanalogue FM satellite systems is FM threshold effect. In FM systems where the signal level is well above noise received carrier-to-noise ratio and demodulated signal-to-noise ratio are related by:

$$S/N \ = \ 3\beta^2\ C/N \qquad Eqn\ 9$$

where

S/N = signal-to-noise ratio at output of FM demodulator
β = FM deviation ratio or modulation index = ($\Delta f/B$)
C/N = carrier-to-noise ratio at input of FM demodulator
Δf = peak deviation
B = basebandwidth of signal being modulated

The expression however does not apply when the carrier-to-noise ratio decreases below a certainpoint.Belowthiscriticalpointthesignal-to-noiseratiodecreasessignificantly.Thisis

known as the FM threshold effect (FM threshold is usually defined as the carrier-to-noise ratio at which the demodulated signal-to-noise ratio fall 1 dB below the linear relationship given in Eqn 9. It generally is considered to occur at about 10 dB).

Below the FM threshold point the noise signal (whose amplitude and phase are randomly varying), may instantaneously have an amplitude greater than that of the wanted signal.When this happens the noise will produce a sudden change in the phase of the FM demodulator output. In an audio system this sudden phase change makes a "click". In video applications the term "click noise" is used to describe short horizontal black and white lines that appear randomly over a picture, because satellite communications systems are power limited they usually operate with only a small design margin above the FM threshold point (perhaps a few dB). Because ofthis circuit designers have tried to devise techniques to delay the onset of the FM threshold effect. These devices are generally known as FM threshold extensiondemodulators.TechniquessuchasFM feedback, phase locked loopsand frequency locked loops are used to achieve this effect. By such techniques the onset of FM threshold effects can be delayed till the C/N ratio is around 7 dB.

NoiseinAngleModulatedSystems

LikeAM, noiseperformanceofanglemodulatedsystems ischaracterizedbyparameter γ

$$\gamma_{FM} = \frac{3}{2}\beta^2$$

If it is compared with AM

$$\frac{\gamma_{FM}}{\gamma_{AM}} = \frac{1}{2}\left(\frac{\omega_{FM}}{\omega_{AM}}\right)^2$$

Note:ifbandwidthratioisincreasedbyafactor2.Then $\frac{\gamma_{FM}}{\gamma_{AM}}$ increasesbyafactor 4

ThisexchangeofbandwidthandnoiseperformanceisanimportantfeatureofFM

$$\text{Figure of merit } (\gamma) = \frac{SNR_O}{SNR_C}$$

CW- Modulation System	SNR_O	SNR_C	Figure of merit	Figure of merit (single tone)
DSB-SC	$\dfrac{C^2 A_c^2 P}{2WN_0}$	$\dfrac{C^2 A_c^2 P}{2WN_0}$	1	1
SSB	$\dfrac{C^2 A_c^2 P}{4WN_0}$	$\dfrac{C^2 A_c^2 P}{4WN_0}$	1	1
AM	$\dfrac{A_c^2 k_a^2 P}{2WN_0}$	$\dfrac{A_c^2 (1+k_a^2 P)}{2WN_0}$	$\approx \dfrac{k_a^2 P}{1+k_a^2 P} < 1$	$\dfrac{\mu^2}{2+\mu^2}$

P is the average power of the message signal.

C^2 is a constant that ensures that the ration is dimensionless.

W is the message bandwidth.

A_c is the amplitude of the carrier signal.

k_a is the amplitude sensitivity of the modulator.

$\mu = k_a A_m$ and A_m is the amplitude sinusoidal wave

$\beta = \dfrac{\Delta f}{W}$ is the modulation index.

k_f is the frequency sensitivity of the modulator.

Δf is the frequency deviation.

UNIT-V

Receivers

Introduction to RadioReceivers:

Inradio communications, a **radio receiver**(**receiver**or simply**radio**) is anelectronic device that receives **radio** waves and converts the information carried by them to a usable form.

Typesof Receivers:

The TRF (Tuned Radio Frequency) Receiver and Superheterodyne Receiver are the two main configurations of the receivers, they have real practical or commercial significance. Most of the present day receivers use superheterodyne configuration. But the TRF receivers are simple and easy to understand.
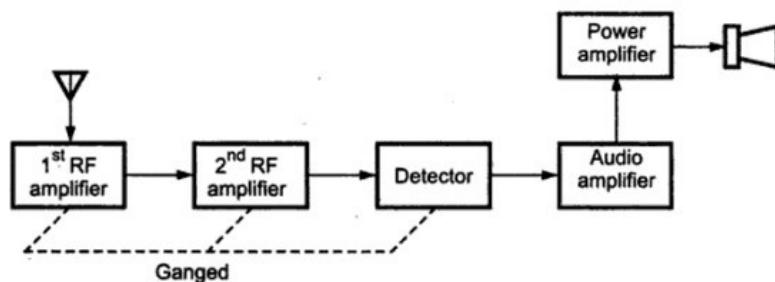

TunedRadioFrequencyReceiver:

Fig. 1 shows the block diagram of TRF receiver.

It consists of two or three stages of RF amplifiers, detector, audio amplifier and

Fig.1.TRFReceiver

power amplifier. The RF amplifier stages placed between the antenna and detector are used to increase the strength of the received signal before it is applied to the detector. These RF amplifiers are tuned to fix frequency, amplify the desired band of frequencies. Therefore, they provide amplification for selected band of frequencies and rejection for all others. As selection and amplification process is carried out in two or three stages and each stage must amplify the same band of frequencies, the ganged tuning is provided.

The amplified signal is then demodulated using detector to recover the modulating signal. The recovered signal is amplified further by the audio amplifier followed by power amplifier which provides sufficient gain to operate a loudspeaker. The TRF receivers suffered from number of annoying problems. These are listed in the next section.

ProblemsinTRFReceivers:

1. Tracking of Tuned Circuit

In a receiver, tuned circuits are made variable so that they can be set to the frequency of the desired signal. In most of the receivers, the capacitors in the tuned circuits are made variable. These capacitors are 'ganged' between the stages so that they all can be changed simultaneously when the tuning knob is rotated. To have perfect tuning the capacitor values between the stages must be exactly same but this is not the case. The differences in the capacitors cause the resonant frequency of each tuned circuit to be slightly different, thereby increasing the pass band.

2. Instability

As high gain is achieved at one frequency by a multistage amplifier, there are more chances of positive feedback (of getting back the small part of output of the last stage at the input to the first with the correct polarity) through some stray path, resulting in oscillations. These oscillations are unavoidable at high frequencies.

3. Variable Bandwidth

TRF receivers suffer from a variation in bandwidth over the tuning range. Consider a medium wave receiver required to tune over 535 kHz to 1640 kHz and it provides the necessary bandwidth of 10 kHz at 535 kHz. Let us calculate Q of this circuit.

$$Q = \frac{f}{\text{Bandwidth}} = \frac{535\,\text{kHz}}{10\,\text{kHz}} = 53.5$$

Now consider the frequency at the other end of the broadcast band, i.e. 1640 kHz. At 1640 kHz, Q of the coil should be 164 (1640 kHz / 10 kHz). However, in practice due to various losses depending on frequency, we will not set so large increase in Q. Let us assume that at 1640 kHz frequency Q is increased to value 100 instead of 164. With this Q of the tuned circuit bandwidth can be calculated as follows

$$\text{Bandwidth} = \frac{f}{Q} = \frac{1640\,\text{kHz}}{100} = 16.4 \text{ kHz}$$

We know, necessary bandwidth is 10 kHz. This increase in bandwidth of tuned circuit, pick up the adjacent stations along with station it is tuned for, providing insufficient adjacent frequency rejection. In other words we can say that in TRF receivers the bandwidth of the tuned circuit varies over the frequency range, resulting in poor selectivity of the receiver.

Because of the problems of tracking, instability and bandwidth variation, the TRF receivers have almost been replaced by superheterodyne receivers.

Superheterodyne Receivers

To solve basic problems of TRF receivers, in these receivers, first all the incoming RF frequencies are converted to a fix lower frequency called **intermediate frequency** (IF). Then this fix intermediate frequency is amplified and detected to reproduce the original information. Since the characteristics of the IF amplifier are independent of the frequency to which the receiver is tuned, the selectivity and sensitivity of superheterodyne receivers are fairly uniform throughout its tuning range.·

Mixer circuit is used to produce the frequency translation of the incoming signal down to the IF. The incoming signals are mixed with the local oscillator frequency signal in such a way that a constant frequency difference is maintained between the local oscillator and the incoming signals. This is achieved by using ganged tuning capacitors.

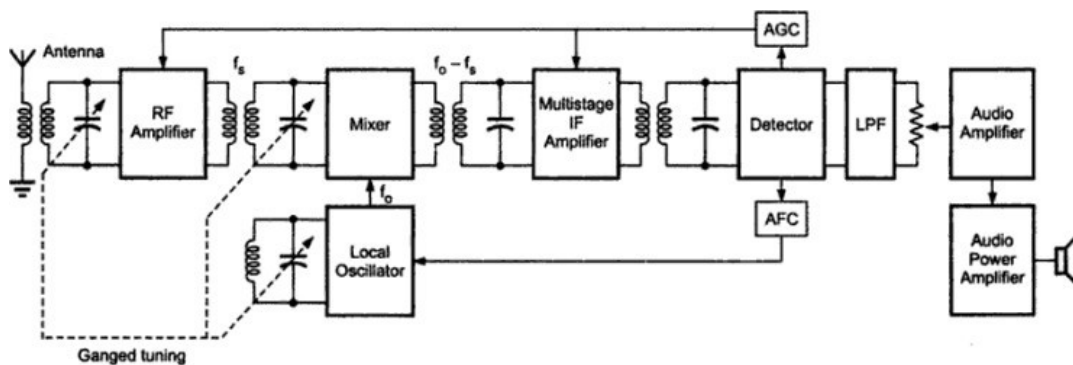

Fig.2.Block diagramofSuperheterodyneReceiver.

Fig. 2   shows the block diagram of superheterodyne receiver. As shown in the Fig. 2   antenna picks up the weak radio signal and feeds it to the RF amplifier. The RF amplifier provides some initial gain and selectivity. The output of the RF amplifier is applied to the input of the mixer. The mixer also receives an input from local oscillator.

The output of the mixer circuit is difference frequency $(f_o - f_s)$ commonly known as IF (Intermediate Frequency). The signal at this intermediate frequency contains the same modulation as the original carrier. This signal is amplified by one or more IF amplifier stages, and most of the receiver gain is obtained in these IF stages.

The highly amplified IF signal is applied to detector circuits to recover the original modulating information. Finally, the output of detector circuit is fed to audio and power amplifier which provides a sufficient gain to operate a speaker.

Another important circuit in the superheterodyne receiver are AGC and AFC circuit. AGC is used to maintain a constant output voltage level over a wide range of RF input signal levels.

It derives the dc bias voltage from the output of detector which is proportional to the amplitude of the received signal. This dc bias voltage is feedback to the IF amplifiers, and sometimes to the RF amplifier, to control the gain of the receiver. As a result, it provides a constant output voltage level over a wide range of RF input signal levels. AFC circuit generates AFC signal which is used to adjust and stabilize the frequency of the local oscillator.

CharacteristicsofRadio Receiver:

The performance of the radio receiver can be measured in terms of following receiver characteristics

- Selectivity
- Sensitivity
- Fidelity
- Image frequency and its rejection
- Double spotting

Selectivity

Selectivity refers to the ability of a receiver to select a signal of a desired frequency while reject all others. Selectivity in a receiver is obtained by using tuned circuits. These are LC circuits tuned to resonate at a desired signal frequency. The Q of these tuned circuits determines the selectivity. Selectivity shows the attenuation that the receiver offers to signals at frequencies near to the one to which it is tuned. A good receiver isolates the desired signal in the RF spectrum and eliminate all other signals.

Recall that Q is the ratio of inductive reactance to resistance ($Q = X_L/R$), and we know that bandwidth of the tuned circuit is given by

$$B_w = \frac{f_r}{Q}$$

where f_r is the resonant frequency. The bandwidth of a tuned circuit is measure of the selectivity. Narrower the bandwidth the better selectivity. To have narrower bandwidth and better selectivity the Q of the tuned circuit must be high.

Sensitivity

The sensitivity of a communication receiver refers to the receivers ability to pick up weak signals, and amplify it. It is often defined in terms of the voltage that must be applied to the receiver input terminals to give a standard output power, measured at the output terminals. The more gain that a receiver has, the smaller the input signal necessary to produce desired output power. Therefore, sensitivity is a primary function of the overall receiver gain. It is often expressed in microvolts or in decibels. The sensitivity of receiver mostly depends on the gain of the IF amplifiers. Good communication receiver has sensitivity of 0.2 to 1μV.

Fidelity

Fidelity refers to the ability of the receiver to reproduce all the modulating frequencies equally. Fig. 3 shows the typical fidelity curve for radio receiver.

The fidelity at the lower modulating frequencies is determined by the low frequency response of the IF amplifier and the fidelity at the higher modulating frequencies is determined by the high frequency response of the IF amplifier. Fidelity is difficult to obtain in AM receiver because good fidelity requires more bandwidth of IF amplifier resulting in poor selectivity.

Fig.3.TypicalFidelitycurve

Image Frequency and its Rejection

In standard broadcast receiver the local oscillator frequency is made higher than the signal frequency by an amount equal to intermediate frequency (IF). Therefore $f_o = f_s + f_i$. When f_o and f_s are mixed, the difference frequency, which is one of the by products, is equal to f_i only f_i is passed and amplified by the IF stage.

If a frequency f_{si} ($f_o + f_i$), i.e. $f_{si} = f_s + 2 f_i$, appears at the input of the mixer then it will produce the sum and difference frequencies regardless of the inputs. Therefore, the mixer output will be the difference frequency at the IF value. The terms f_{si} is called the **image** frequency and is defined as the signal frequency plus twice the intermediate frequency. Unfortunately, this image frequency signal is also amplified by the IF amplifiers resulting in interference. This has the effect of two stations being received simultaneously and is naturally undesirable.

The rejection of an image frequency by a single tuned circuit is the ratio of the gain at the signal frequency to the gain at the image frequency. It is given by

$$\alpha = \sqrt{1 + Q^2 \rho^2}$$

where $\quad \rho = \dfrac{f_{si}}{f_s} - \dfrac{f_s}{f_{si}}$

and $\quad Q = $ loaded Q of tuned circuit

If the receiver has an RF stage, then there are two tuned circuits, both tuned to f_s ; the rejection of each will be calculated by the same formula, and the total rejection will be the product of two.

The image rejection depends on the selectivity of the RF amplifier and tuned circuits and must be achieved before the IF stage. Once the spurious frequency enters the first IF amplifier, it becomes impossible to remove it from the wanted signal.

Double Spotting

The phenomenon of double spotting occurs at higher frequencies due to poor front end selectivity of the receivers. In this, receiver picks up same short-wave station at two nearby points on the receiver dial.

When the receiver is tuned across the band, a strong signal appears to be at two different frequencies, once at the desired frequency and again when the receiver is tuned to 2 times IF below the desired frequency. In this second case, the signal becomes the image, reduced in strength by the image rejection, thus making it appear that the signal is located at two frequencies in the band.

1. RF Amplifier:

RF amplifier provides initial gain and selectivity. Fig. 4 shows the RF amplifier circuits. It is a tuned circuit followed by an amplifier The RF amplifier is usually a simple class A circuit. A typical bipolar circuit is shown in Fig. 4. (a), and a typical FET circuit is shown in Fig. 4. (b).

(a)   (b)
The values of resistors R_1 and R_2 in the bipolar circuit are adjusted such that the amplifier works as class A amplifier. The antenna is connected through coupling capacitor to the base of the transistor. This makes the circuit very broad band as the transistor will amplify virtually any signal picked up by the antenna. However the collector is tuned with a parallel resonant circuit to provide the initial selectivity for the mixer input.

The FET circuit shown in Fig. 4 (b) is more effective than the transistor circuit. Their high input impedance minimizes the loading on tuned circuits, thereby permitting the Q of the circuit to be higher and selectivity to be sharper.

The receiver having an RF amplifier stage has following advantages :

1. It provides greater gain, i.e. better sensitivity.

2. It improves image-frequency rejection.

3. It improves signal to noise ratio.

4. It improves rejection of adjacent unwanted signals, providing better selectivity.

5. It provides better coupling of the receiver to the antenna.

6. It prevents spurious frequencies from entering the mixer and heterodyning there to produce an interfering frequency equal to the IF from the desired signal.

7. It also prevents reradiation of the local oscillator through the antenna of the receiver.

2. Mixer

The frequency converter is a nonlinear resistance having two sets of input terminals and one set of output terminal. The two inputs to the frequency converter are the input signal along with any modulation and the input from a local oscillator (LO). The output contains several frequencies including the difference between the input frequencies. The difference frequency is called intermediate frequency and output circuit of the mixer is tuned for the intermediate frequency.
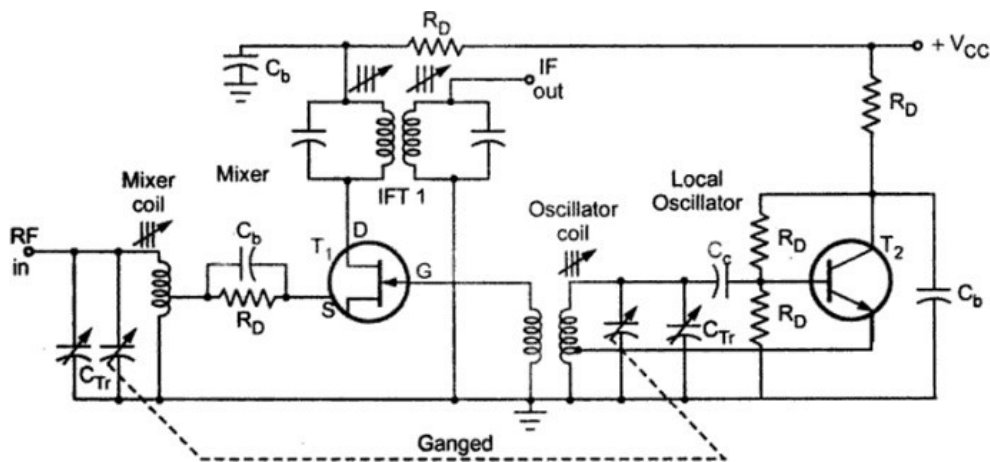

SeparatelyExcitedMixer:

Fig.5SeparatelyExcitedFETMixer

Fig. 5 shows the separately excited mixer using FET. Here, one device acts as a mixer while the other supplies the necessary oscillations. The bipolar transistor T_2, forms the Hartley oscillator circuit. It oscillates with local frequency (f_o). FET T_1, is a mixer, whose gate is fed with the output of local oscillator and its bias is adjusted such that it operates in a nonlinear portion of its characteristic. The local oscillator varies the gate bias of the FET to vary its transconductance in a nonlinear manner, resulting intermediate frequency (IF) at the output. The output is taken through double tuned transformer in the drain of the mixer and fed to the IF amplifier. The ganged tuning capacitor allows simultaneous tuning of mixer and local oscillator.

The C_{Tr}, a small trimmer capacitors across each of the tuning capacitors are used for fine adjustments.

SelfExcited Mixer:

It is possible to combine the function of the mixer and local oscillator in one circuit. The circuit is commonly known as self excited mixer. Fig. 6 shows self excited bipolar transistor mixer. The circuit oscillates and the transconductance of the transistor is varied in a nonlinear manner at the local oscillator rate. This variable transconductance (g_m) is used by the transistor to amplify the incoming RF signal.

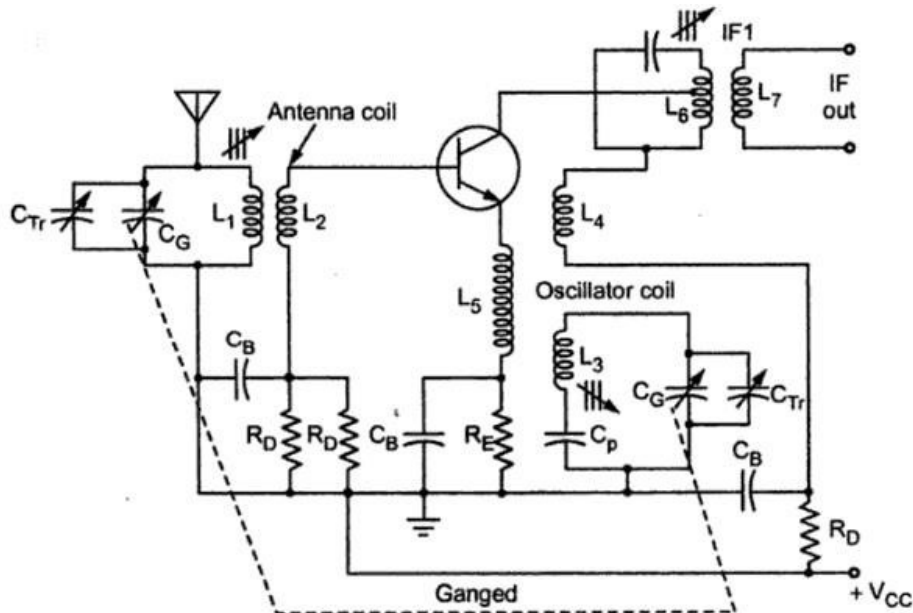

Fig.6.SelfExcitedMixer

3. Tracking

The superheterodyne receiver has number of tunable circuits which must all be tuned correctly if any given station is to be received. The ganged tuning is employed to do this work, which mechanically couples all tuning circuits so that only one tuning control or dial is required. Usually, there are three tuned circuits : Antenna or RF tuned circuit, mixer tuned circuit and local oscillator tuned circuit. All these circuits must be tuned to get proper RF input and to get IF frequency at the output of mixer. The process of tuning circuits to get the desired output is called **Tracking**. Any error that exists in the frequency difference will result in an incorrect frequency being fed to the IF amplifier. Such errors are known as 'Tracking Errors' and these must be avoided.

To avoid tracking errors standard capacitors are not used, and ganged capacitors with identical sections are used. A different value of inductance and special extra capacitors called trimmers and padders are used to adjust the capacitance of the oscillator to the proper range. There are three common methods used for tracking. These are

- Padder tracking
- Trimmer tracking

4. LocalOscillator

In shortwave broadcasting, the operating limit for receivers is 36 MHz. For such operating limit local oscillators such as Armstrong, Hartley, Colpitts, Clapp or ultra-audion are used. The Colpitts, Clapp and ultra-audion oscillators are used at the top of the operating limit, whereas Hartley oscillator is used for frequencies below 120 MHz. All these oscillators are LC oscillators and each employs only one tuned circuit to defermine its frequency. When higher frequency stability of local oscillator is required, the circuits like AFC (Automatic Frequency Control) are used.

5. IFAmplifier

IF amplifiers are tuned voltage amplifiers tuned for the fixed frequency. Its important function is to amplify only tuned frequency signal and reject all others. As we know, most of the receiver gain is provided by the IF amplifiers, to obtain required gain, usually two or more stages of IF amplifiers are required.

Fig. 7 shows the two stage IF amplifier. Two stages are transformer coupled and all IF transformers are single tuned, i.e. tuned for single frequency.
Fig.7 TwoStageIFAmplifier

ChoiceofIntermediate Frequency:

Selection of the intermediate frequency depends on various factors. While choosing the intermediate frequency it is necessary to consider following factors.

1. Very high intermediate frequency will result in poor selectivity and poor adjacent channel rejection.

2. A high value of intermediate frequency increases tracking difficulties.

3. At low values of intermediate frequency, image frequency rejection is poor.

4. At very low values of intermediate frequency, selectivity is too sharp. Cutting off the sidebands.

5. At very low IF, the frequency stability of the local oscillator must be correspondingly high because any frequency drift is now a larger proportion of the low IF than of a high IF.

6. The IF must not fall in the tuning range of the receiver, otherwise instability will occur and heterodyne whistles will be heard, making it impossible to tune to the frequency band immediately adjacent to the intermediate frequency.

With the above considerations the standard broadcast AM receivers [tuning to 540 to 1650 kHz] use an IF within the 438 kHz to 465 kHz range. The 465 kHz IF is most commonly used.

6. AutomaticGain Control

Automatic Gain Control is a system by means of which the overall gain of a radio receiver is varied automatically with the variations in the strength of the receiver signal, to maintain the output substantially constant. AGC circuitry derives the dc bias voltage from the output of the detector. It applies this derived dc bias voltage to a selected number of RF, IF and mixer stages to control their gains. When the average signal level increases, the size of the AGC bias increases, and the gain of the controlled stages decreases. When there is no signal, there is a minimum AGC bias, and the amplifiers produce maximum gain. There are two types of AGC circuits in use : Simple AGC and Delayed AGC

Simple AGC

In simple AGC receivers the AGC bias starts to increase as soon as the received signal level exceeds the background noise level. As a result receiver gain starts falling down, reducing the sensitivity of the receiver.

Fig.8.SimpleAGCcircuit

Fig. 8 shows the simple AGC circuit. In this circuit, dc bias produced by half wave rectifier as a AM detector, is used to control the gain of RF or IF amplifier. Before application of this voltage to the base of the RF and / or IF stage amplifier the audio signal is removed by the lowpass filter. The time constant of the filter is kept at least 10 times longer than the period of the lowest modulation frequency received. If the time constant is kept longer, it will give better filtering, but it will cause an annoying delay in the application of the AGC control when tuning from one signal to another. The recovered signal is then passed through C_C to remove the dc. The resulting ac signal is further amplified and applied to the loudspeaker.

Delayed AGC

Simple AGC is clearly an improvement over no AGC at all. Unfortunately, in simple AGC circuit, the unwanted weak signals(noise signals) are amplified with high gain. To
Fig.9.DelayedAGC circuit

avoid this, in delayed AGC circuits, AGC bias is not applied to amplifiers until signal strength has reached a predetermined level, after which AGC bias is applied as with simple AGC, but more strongly.

Here, AGC output is applied to the difference amplifier. It gives negative dc AGC only when AGC output generated by diode detector is above certain dc threshold voltage. This threshold voltage can be adjusted by adjusting the voltage at the positive input of the operational amplifier.
Fig.10. Responseofreceiverwithvarious AGCcircuits.

FMReceiver:

Fig.11.FMReceiverBlock diagram

The FM receiver is a superheterodyne receiver, and the block diagram of Figure **11** shows just how similar it is to an AM receiver. The basic differences are as follows:

1. Generally much higher operating frequencies in FM
2. Need for limiting and de-emphasis in FM
3. Totally different methods of demodulation
4. Different methods of obtaining AGC

Comparisonswith AMReceivers

A number of sections of the FM receiver correspond exactly to those of other receivers already discussed. The same criteria apply in the selection of the intermediate frequency, and IF amplifiers are basically similar. A number of concepts have very similar meanings so that only the differences and special applications need be pointed out.

RF amplifiers An RF amplifier is always used in an FM receiver. Its main purpose is to reduce the noise figure, which could otherwise be a problem because of the large bandwidths needed for FM. It is also required to match the input impedance of the receiver to that of the antenna. To meet the second requirement, grounded gate (or base) or cascode amplifiers are employed. Both types have the property of low input impedance and matching the antenna, while neither requires neutralization. This is because the input electrode is grounded on either type of amplifier, effectively isolating input from output. A typical FET grounded-gate RF amplifier is shown in Figure
It has all the good points mentioned and the added features of low distortion and simple operation.
FIGURE   **Grounded-gate FET RF amplifier.**

Oscillators and mixers The oscillator circuit takes any of the usual forms, with the Colpitts and Clapp predominant, being suited to VHF operation. Tracking is not normally much of a problem in FM broadcast receivers. This is because the tuning frequency range is only 1.25:1, much less than in AM broadcasting.

A very satisfactory arrangement for the front end of an FM receiver consists of FETs for the RF amplifier and mixer, and a bipolar transistor oscillator. As implied by this statement, separately excited oscillators are normally used .

Intermediate frequency and IF amplifiers   Again, the types and operation do not differ much from their AM counterparts. It is worth noting, however, that the intermediate frequency and the bandwidth required are far higher than in AM broadcast receivers. Typical figures for receivers operating in the 88- to 108-MHz band are an IF of 10.7 MHz and a bandwidth of 200 kHz. As a consequence of the large bandwidth, gain per stage may be low. Two IF amplifier stages are often provided, in which case the shrinkage of bandwidth as stages are cascaded must be taken into account.

Double limiter

A double limiter consists of two amplitude limiters in cascade, an arrangement that increases the limiting range very satisfactorily. Numerical values given to illustrate limiter performance showed an output voltage (all values peak-to-peak, as before) of 5 V for any input within the 0.4- to 4-V range, above which output gradually decreases. It is quite possible that an output of 0.6 V is not reached until the input to the first limiter is about 20 V. If the range of the second limiter is 0.6 to 6 V, it follows that all voltages between 0.4 and 20 V fed to the double limiter will be limited. The use of the double limiter is seen to have increased the limiting range quite considerably.

Automatic gain control (AGC)

A suitable alternative to the second limiter is automatic gain control. This is to ensure that the signal fed to the limiter is within its limiting range, regardless of the input signal strength, and also to prevent overloading of the last IF amplifier. If the limiter used has leak-type bias, then this bias voltage will vary in proportion to the input voltage (as shown in Figure 6-31) and may therefore be used for AGC. Sometimes a separate AGC detector is used, which takes part of the output of the last IF amplifier and rectifies and filters it in the usual manner.

AmplitudeLimiter:

In order to make full use of the advantages offered by FM, a demodulator must be preceded by an amplitude limiter,   on the grounds that any amplitude changes in the signal fed to the FM demodulator are spurious

They must therefore be removed if distortion is to be avoided. The point is significant, since most FM demodulators react to amplitude changes as well as frequency changes. The limiter is a form of clipping device, a circuit whose output tends to remain constant despite changes in the input signal. Most limiters behave in this fashion, provided that the input voltage remains within a certain range. The common type of limiter uses two separate electrical effects to provide a relatively constant output. There are leak-type bias and early (collector) saturation.

Operation of the amplitude limiter Figure   shows a typical FET amplitude limiter. Examination of the dc conditions shows that the drain supply voltage has been dropped through resistor R_D. Also, the bias on the gate is leak-type bias supplied by the parallel $R_g - C_g$ combination. Finally, the FET is shown neutralized by means of capacitor C_N, in consideration of the high frequency of operation.
FIGURE   Amplitude limiter.

Leak-type bias provides limiting, as shown in Figure   . When input signal voltage rises, current flows in the $R_g - C_g$ bias circuit, and a negative voltage is developed across the capacitor. It is seen that the bias on the FET is increased in proportion to the size of the input voltage. As a result, the gain of the amplifier is lowered, and the output voltage tends to remain constant.

Although some limiting is achieved by this process, it is insufficient by itself, the action just described would occur only with rather large input voltages. To overcome this, early saturation of the output current is used, achieved by means of a low drain supply voltage. This is the reason for the drain dropping resistor of Figure   . The supply voltage for a limiter is typically one-half of the normal dc drain voltage. The result of early saturation is to ensure limiting for conveniently low input voltages.
FIGURE   Amplitude limiter transfer characteristic.

It is possible for the gate-drain section to become forward-biased under saturation conditions, causing a short circuit between input and output. To avert this, a resistance of a few hundred ohms is placed between the drain and its tank. This is *R* of Figure
PULSEMODULATION

Introduction:

PulseModulation

- Carrierisatrainofpulses
- Example:PulseAmplitudeModulation(PAM),Pulsewidthmodulation(PWM), Pulse Position Modulation (PPM)

TypesofPulse Modulation:

- Theimmediateresultofsamplingisapulse-amplitudemodulation(PAM)signal

- PAM isananalogscheme inwhichtheamplitude ofthepulse isproportionaltothe amplitude of the signal at the instant of sampling

- Anotheranalogpulse-formingtechniqueisknownas**pulse-durationmodulation (PDM).** This is also known as **pulse-width modulation (PWM)**

- **Pulse-positionmodulation**iscloselyrelatedtoPDM

PulseAmplitudeModulation:

In PAM, amplitude of pulses is varied in accordance with instantaneous value of modulating signal.

PAMGeneration:

The carrier is in the form of narrow pulses having frequency fc. The uniformsampling takes place in multiplier to generate PAM signal. Samples are placed Ts sec away from each other.
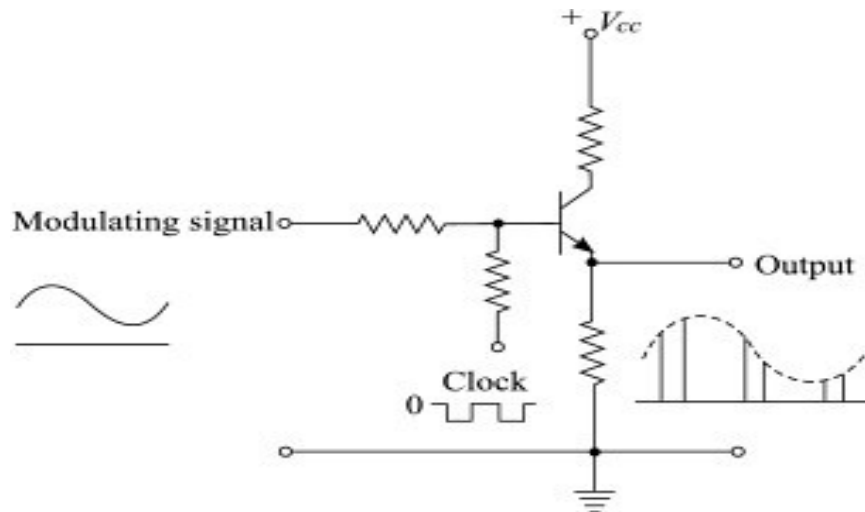

Fig.12.PAMModulator

● Inthe absenceoftheclock signal,theoutput followsinput.

● Themodulatingsignalisappliedastheinputsignal.

● Anotherinputtothe baseofthetransistoristhe clocksignal.

● The frequency of the clock signal is made equal to the desired carrier pulse train frequency.

● The amplitude of the clock signal is chosen the high level is at ground level(0v) and low levelat some negative voltage sufficient to bring the transistor in cutoff region.

● When clock is high, circuit operates as emitter follower and the output follows in the input modulating signal.

● Whenclocksignalis low, transistor iscutoffandoutputis zero.

● ThustheoutputisthedesiredPAMsignal.

PAMDemodulator:

● The PAM demodulator circuit which is just an envelope detector followed by asecond order op-amp low pass filter (to have good filtering characteristics) is asshown below

Fig.13. PAMDemodulator

PulseWidthModulation:

- Inthistype, the amplitude is maintained constant but the widthofeachpulse is varied in accordance with instantaneous value of the analog signal.

- InPWM informationiscontainedinwidthvariation. This issimilartoFM.

- Inpulsewidthmodulation(PWM),thewidthofeachpulseismadedirectly proportional to the amplitude of the information signal.

PulsePosition Modulation:

- Inthistype,thesampledwaveformhasfixedamplitudeandwidthwhereastheposition of each pulse is varied as per instantaneous value of the analog signal.

- PPMsignalis furthermodificationofaPWMsignal.

PPM& PWMModulator:

Fig.14.PWM&PPM Modulator

- ThePPMsignalcan begenerated fromPWMsignal.

- ThePWMpulsesobtainedatthecomparatoroutputareappliedto amono stable multi vibrator which is negative edgetriggered.

- Hence foreachtrailingedgeofPWMsignal,the monostableoutputgoeshigh.It remains high for a fixed time decided by its RC components.

- Thusasthetrailingedgesofthe PWMsignalkeepsshifting inproportionwiththe modulating signal, the PPM pulses also keep shifting.

- ThereforeallthePPMpulseshavethesameamplitudeandwidth.The informationis conveyed via changing position of pulses.

PWMDemodulator:

Fig.16.PWMDemodulator

- TransistorT1works asaninverter.

- During timeinterval A-B when the PWM signal is high theinput to transistor T2 islow.

- Therefore, during this time interval T2 is cut-off and capacitor C is charged throughan R-C combination.

- During time interval B-C when PWM signal is low, the input to transistor T2 is high, and it gets saturated.

- The capacitor C discharges rapidly through T2.The collector voltage of T2 during B-C is low.

- Thus,thewaveformatthecollectorofT2issimilartosaw-toothwaveformwhose envelope is the modulating signal.

- Passingitthrough2^{nd}orderop-ampLowPassFilter,givesdemodulatedsignal.
PPMDemodulator:

Fig.17.PPMDemodulator

- The gaps between the pulses of a PPM signal contain theinformation regarding themodulating signal.

- During gap A-B between the pulses the transistor is cut-off and the capacitor C getscharged through R-C combination.

- DuringthepulsedurationB-Cthecapacitordischargesthroughtransistorandthe collector voltage becomes low.

- Thus,waveformacrosscollectorissaw-toothwaveformwhoseenvelopeisthe modulating signal.
